INTERAGENCY REGULATORY LIAISON GROUP (IRLG) Washington, D.C.

NOTICE TO USERS

On September 28, 1981, the formation of the Regulatory Work Group on Science and Technology was announced. Members include the agency heads of the Consumer Product Safety Commission, the Environmental Protection Agency, The Food and Drug Administration, The Food Safety and Inspection Service, and Occupational Safety and Health Administration. The chairman is Dr. George A. Keyworth, Director of the Office of Science and Technology Policy, Office of the President. The purpose of this Work Group is to strengthen the role of scientific data and analysis in the regulatory process.

Concurrent with the formation of this Group, it was decided not to renew the agreement which established the Interagency Regulatory Liaison Group (IRLG). This agreement expired at the end of September 1981. As a result, the Epidemiology Research Projects Directory, supported by the IRLG, will no longer be published. As a service to current users of the Directory, it was decided to combine data on ongoing epidemiology research projects for both 1980 and 1981 in a single publication rather than to terminate this activity with Volume 2 (1980) alone. Volumes 2 and 3 are, thus, both contained in this final publication.

FOREWORD

The *Epidemiology Research Projects Directory* (ERPD) is sponsored and funded by the Interagency Regulatory Liaison Group (IRLG) which is composed of the U.S. Consumer Product Safety Commission (CPSC), Food and Drug Administration (FDA), Food Safety and Quality Service (FSQS), Environmental Protection Agency (EPA) and Occupational Safety and Health Administration (OSHA). The IRLG was organized in 1977 to improve the public health through sharing of information, avoiding duplication of effort, and developing consistent regulatory policy through compatible practices in areas of activity common to the Agencies. The IRLG and its Epidemiology Work Group (EWG) hope that this *Directory* will serve as a central reference location for current epidemiological studies and, thus, increase the availability of the state-of-the-art knowledge concerning current epidemiological projects on adverse health effects resulting from diverse exposures. Regulatory decisionmaking should be enhanced by the facilitation of regulatory statutes implementation based on adequate scientific data which will identify gaps in knowledge, reduce redundancy and overlaps, and stimulate further pertinent investigations and studies. Information needs of non-Government researchers and administrators concerned with environmental hazards should also be fulfilled with scientific input useful for formulating their problems, resolving their courses of action, and improving their capability to assess risks and benefits of regulatory rules.

The *Epidemiology Research Projects Directory* is also the result of cooperation with another interagency committee, the DHHS Committee to coordinate Environmental and Related Programs (CCERP).

Both interagency committees wish to increase awareness of ongoing and planned research in epidemiology and toxicology and thus avoid possible unnecessary duplication of expensive research which would waste scarce resources. They hope to facilitate the identification of organizations supporting or performing research in these subject areas. This may be accomplished through the use of the Sponsoring Organization and Performing Organization Indexes.

The two interagency groups are also making available these epidemiology and toxicology data bases through an online system—Toxline—via a new index term, RPROJ. (Please see the User Guide, page iv.)

Epidemiology research projects include those related to morbidity and mortality; occupational, consumer, and other population exposure to various hazards; biologic, pharmacologic, and environmental research on susceptibility to disease; and illnesses related to chemical exposure.

USER GUIDE

The *Epidemiology Research Projects Directory* is an annual publication of ongoing research projects in epidemiology selected from the files of the Smithsonian Science Information Exchange (SSIE).

Each project summary is categorized by scientific discipline and assigned a unique identification number for cross-referencing from the Directory Indexes—Subject, Investigator, Performing Organization, Supporting Agency, and Master Grant Number.

The emphasis of the Directory is on the relationship between a causal factor and the resultant human disease or problem. The cause may be an environmental, chemical, physical, or microbiological hazard, or it may be genetic, social, or behavioral. The resulting disease or condition may be a physiological or mental pathology or a destructive addiction. Studies of the use of animals to prove a theory of cause and effect have been excluded, but animals as vectors or reservoirs of human diseases have been included. Techniques for determining environmental hazards have been included only when a direct application to human exposure is to be made.

The **Description of Research Projects** contains all the project summaries in the Directory arranged by supporting organization.

The **Subject Index** is based on a classification system developed by SSIE in which index terms are arranged in hierarchies indicating relationships between broader and narrower subject areas. Related terms are thus grouped together under broader terms. Each index term is followed by the project title and a five-digit number (ie, 1.0001) indicating the specific location of each project indexed to that term.

The indexing is as specific as the project permits. A study dealing with the epidemiology of illness due to inhaled asbestos would be indexed to "Asbestos" under a hierarchy consisting of "Irritants-particulates" which in turn could be found under the broader term "Respiratory System". "See" and "See Also" cross-references are provided in the subject index to indicate the hierarchies where specific terms may be found. For instance, alphabetically within the subject index would be listed the term "Asbestos" with the reference "See Also Respiratory System Irritants-particulates". To further aid the reader in locating subject material, the subject index pages use a dictionary format: the first high-level term appearing on a left-hand page is printed in the upper left-hand corner of that page; the last high-level term on the right-hand page appears on the upper right-hand corner of that page.

The **Investigator Index** is an alphabetic listing of all investigators cited on the source document provided to SSIE. An asterisk is used to designate an individual specified as principal investigator; due to space limitations only this name appears on the project summary.

The **Performing Organization Index** lists alphabetically the name of the institution or laboratory actually conducting the investigation.

The Supporting Agency Index consists of a single alphabetical listing of both Federal and non-Federal sources of support. This index also uses "See" references (as in the subject index) to assist the user in locating major organizational units within the U.S. Government (i.e., FDA within USDHHS). In view of the large number of state agencies and departments, they are displayed as a combined group under each state. The Master Grant Number Index. Within the Projects Section are included a few reports that have no summary, but are referenced in the description of an encompassing master grant. The summary for this larger program grant to which a subproject is referred may be located by using this index.

The contents of the *Epidemiology Research Projects Directory* are also available through an online system—Toxline—via a new index term, RPROJ. Subscribers to the National Library of Medicine's Toxline file may now search for epidemiology and toxicology research abstracts in RPROJ, which is updated monthly.

Projects identified in the *Epidemiology Research Projects Directory* by D-IARC were originally collected by the International Agency for Research on Cancer (IARC) and are listed in a *Directory of On-Going Research in Cancer Epidemiology* which is published annually by IARC and the Germany Cancer Research Center in Heidelberg. This activity is supported by the International Cancer Research Data Bank Program of the National Cancer Institute.

For information about subscribing to or using this new Toxline subfile, RPROJ, please contact the Toxicology Information Program, Specialized Information Services, National Library of Medicine, Building 38A C6B, 8600 Rockville Pike, Bethesda, MD 20209. Telephone (301) 496-1131.

SAMPLE PROJECT SUMMARY

Project Title

NAVY ENVIRONMENT: HEALTH EFFECTS OF ASBESTOS EXPOSURE AMONG PEARL HARBOR NAVAL SHIPYARD WORKERS

Principal Investigator
Affiliation & Address
Grant or Contract Number

L. N. Kolonel, University of Hawaii System, Manoa Campus, Cancer Center of Hawaii, 1997 East West Rd.; Honolulu, Hawaii 96822 (DN675593) (N00014-76-C-0952)

Project Description

This study is to assess disease risks associated with varying degrees of asbestos exposure in a naval shipyard. The effect of smoking and other adverse respiratory exposures on these risks will be evaluated.

Asbestos exposure and disease incidence are being examined in a population of workers with primary exposure to one fiber type whose characteristics of small diameter and straight fibers permit deep penetration into the lungs. Detailed historical information regarding smoking habits and toxic exposures is being obtained by questionnaires. Measurements of air concentrations of asbestos fibers are being made with individual samples worn near the breathing zone. Diagnosis of all pulmonary and any suspicious intra-abdominal tumors in the workers will be confirmed by microscopic examination of the involved tissues. All data collected will be keypunched and stored on computer tape for analysis.

DESCRIPTION OF RESEARCH PROJECTS

2.0001,

STUDIES ON THE FREQUENCY AND INCIDENCE OF LYMPHOMA AND LEUKEMIA IN TWINS

E.R. Brown, University of Health Sciences - Chicago Medical School, Medical School, Dept. of Microbiology, *2020 W. Ogden Ave., Chicago, Illinois* 60612 (D-IARC-79-801)

The project relates to the higher incidence of lymphomas and leukemias found in twins, and breaks this down into the type, age, sex, etc. of the twins.

2.0003,

EPIDEMIOLOGY OF CANCER AMONG MORMONS

L. Breslow, University of California, Los Angeles Campus, School of Public Health, Dept. of Public Health, *405 Hilgard Ave., Los Angeles, California* 90024 (PDT-51B)

Results ascertained by us for 350,000 California Mormons during 1968-75 and 750,000 Utah Mormons during 1970 and 1975 compared with U.S. whites show that the standardized mortality ratio (SMR) for total cancer is about 50 percent for active males, about 65 percent for all males, and about 75 percent for all females. For active males the SMR is about 25 percent for smoking-related cancer sites and about 65 percent for all other sites. Mormons are a health-conscious religious group, who appear to be similar to U.S. whites in many respects, such as, diet, socioeconomic status, and urbanization, but who use substantially less tobacco, alcohol, coffee, and tea than the general population. Active Mormons, defined here to be Church leaders known as High Priests and Seventies, abstain almost entirely from these substances. However, the reasons for the low Mormon cancer rates are largely unknown, primarily because there is no detailed data available on their health-related characteristics.

The objective now is to pursue this descriptive mortality data with a questionnaire survey and prospective mortality follow-up of active California Mormon adults, specifically High Priests and their wives. The survey will obtain detailed demographic, lifestyle, dietary, occupational, and medical history data on a representative sample of about 1000 individuals and limited demographic and lifestyle information on about 20,000 additional individuals. Mortality follow-up will be conducted on this active Mormon cohort for four years. Additional Church-based mortality data will be collected for all California Mormons during the years 1960-67 and 1976-79 and for all Utah Mormons during 1976-79 to increase the statistical reliability of the existing data summarized above.

The data on aggregate lifestyle and health-related characteristics of active California Mormons will be combined with their detailed cancer mortality rates. Distinctive differences between these Mormons and other comparison groups will be highlighted. Using variation in characteristics other than smoking and drinking, major subgroups of active Mormon questionnaire respondents will be defined and compared for subsequent mortality. These analyses should provide significant understanding as to why Mormons have low cancer mortality rates.

2.0004,

EPIDEMIOLOGY OF LARGE BOWEL CANCER IN WOMEN

N.S. Weiss, Fred Hutchinson Cancer Research Center, Epidemiology & Biostatistics Program, *1124 Columbia St., Seattle, Washington* 98104 (PDT-96A)

A short extension of the case-control study is being proposed to test the hypothesis that use of menopausal estrogens offers relative protection against the development of large bowel cancer. All 35-74 year old female residents of King and Pierce Counties (Washington) who are diagnosed as having large bowel cancer during a 15-month period are to be interviewed concerning exogenous hormone exposure and menstrual and reproduction experience. Their responses will be compared to those of healthy women randomly selected from the population of these same counties.

SUPPORTED BY American Cancer Society Inc. $17,936

2.0005,

BREAST CANCER IN CONNECTICUT MOTHERS EXPOSED DURING PREGNANCY TO EXOGENOUS ESTROGENS

J.W. Meigs, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (PDT-144)

The aim of this research is to examine the claim that the administration of exogenous estrogens to women during pregnancy has increased their risks of cancer. The question of breast cancer risk will be examined intensively by expanding the objectives and extending the procedures of the Connecticut Diethylstilbestrol Cohort Study now in progress (NCI Grant #5 R01 CA 20347). The general method is to identify cohorts of exposed women and otherwise comparable non-exposed women by reviewing prenatal records from cooperating Connecticut obstetrician-gynecologists and to identify their breast cancer experience through the Connecticut Tumor Registry. A second control group, a stratified random sample of Connecticut mothers, are being selected using birth registration data. Cancer experience will be identified in an identical manner for this cohort. To determine person-years-at-risk of breast cancer subject to report to the Connecticut Tumor Registry, detailed follow-up procedures involving searches of City Directories and Motor Vehicle license files will be conducted for all subjects. Breast cancer incidence among the control mother cohorts will be compared to that in the at-risk group. In addition, the integrated and expanded study will complete the estimates of risk to offspring from prenatal exposures to exogenous estrogens.

SUPPORTED BY American Cancer Society Inc. $78,348

2.0006,

MINERAL FIBERS AND LUNG CANCER

A.M. Churg, University of California, San Francisco Campus, School of Medicine, Dept. of Pathology, *551 Parnassus Ave., San Francisco, California* 94122 (PDT-146)

Epidemiologic studies of lung cancer indicate that there are marked incidence variations which cannot be accounted for by cigarette smoking patterns, but do appear to relate to variables such as race, socioeconomic status, and geographic location. Air pollution is another factor which has sometimes been implicated in lung carcinogenesis, primarily on the basis of urban vs. rural cancer rates. Mineral fibers constitute a portion of the particulate fraction of urban air pollution, and it has been shown in animal studies that, under appropriate conditions, many particulates and especially mineral fibers may be carcinogenic or co-carcinogenic. Mineral fibers are known to be present in large numbers in the lungs of urban dwellers. This grant request involves an investigation to determine if there is an association between lung burden of fibrous minerals and bronchogenic carcinoma in general urban population in a geographically high lung cancer area. Numbers of mineral fibers will be quantitated at the light and electron microscopic level by dissolving autopsy and surgical lungs and collecting appropriate samples. Whole lung slices will be used to minimize topographic variation in numbers of fibers. Fibers will be further identified by electron diffraction and electron microprobe to determine mineral species, and will also be enumerated by lengths and diameters; the latter properties appear to be important in carcinogenesis. An attempt will be made to correlate total fibers, fiber specific mineral type, and/or fibers of various size classes with the presence or absence of bronchogenic carcinoma.

2.0007,

IMMUNOLOGIC/EPIDEMIOLOGIC STUDY OF HODGKIN'S DISEASE

F.P. Siegal, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (PDT-153)

The proposed research will investigate three aspects of the epidemiology and immunology of Hodgkin's Disease. Tissue antigens will be sought which are specifically stimulatory to lymphocytes of patients, their families and close personal contacts but not of appropriately-matched controls, to define the potential for transmission of a hypothetical agent. The same subjects will be evaluated to determine if there is a component of the immunodeficiency associated with Hodgkin's which is communicable, and might be secondary to the disease. To better understand susceptibility factors in Hodgkin's, B lymphocyte typing for Ia-like antigens will be done as well. Through this combined analysis, with its emphasis on the study of related and unrelated contacts, rather than patients (who might be expected not to respond well to Hodgkin's associated antigens) it is hoped that clues might be found which would help define the pathogenesis of the disease.

TRANSIENT CEREBRAL ISCHEMIC AND EMBOLIC STROKE

R.I. Pfeffer, University of California, Irvine Campus, California College of Medicine, Dept. of Neurology, *Irvine, California* 92664

The association between transient cerebral ischemic attack (TIA) and embolic cerebral infarction will be examined in a large free-living population. Previous studies do not describe the mechanism of stroke in a large, unselected group of persons who suffer TIA, but only link TIA to embolic infarction anecdotally. All TIA and cerebral infarction affecting a cohort of 11,000 persons over a three-year period will be ascertained. Cases of cerebral infarction will be classifed as embolic (cardiac origin), embolic (noncardiac origin), nonembolic, lacunar, or indeterminate after careful review of clinical and laboratory data. The proportion of persons with embolic infarction of noncardiac origin and of persons with nonembolic infarction who did and did not experience a preceding TIA will be compared. Associations will also be evaluated in subclasses of TIA, based upon characteristics of the attacks such as vascular distribution affected, duration, and multiplicity of attacks.

Persons with TIA are an identifiable population for further diagnostic study and preventive intervention. If embolism were the major risk in TIA patients, the hazards of angiography and surgery might be avoided in many such persons. Alternatively, evidence of occlusive disease would justify major efforts at noninvasive detection of extracranial stenosis. Subpopulations at differential risk: e.g., carotid TIA should be considered separately in future therapeutic trials.

2.0009,

INVESTIGATION OF HDL-CHOLESTEROL IN CHRONIC DISEASE AND ESTABLISHMENT OF NORMAL VALUES IN A HEALTH PLAN POPULATION

A.G. Scottolini, Kaiser Foundation Hospital, Dept. of Pathology & Clinical Laboratories, *1697 Ala Moana Blvd., Honolulu, Hawaii* 96815

The inverse relationship between HDL-cholesterol and coronary heart disease has been well established, i.e., a high HDL-cholesterol is protective whereas a low one may place a patient at risk. However, the relationship between predisposing diseases, e.g., diabetes mellitus, hypothyroidism, etc., has not been investigated. Simplified methodology (polyanion precipitation techniques) while currently available is not part of the routine clinical laboratory. As a matter of fact, to my knowledge the technique is not available anywhere in the state of Hawaii except at our own facility. The Kaiser Permanente Health Care Program has over 107,000 subscribers in the state of Hawaii. They generate 400,000 clinic visits and 11,000 multiphasic health examinations annually. Since most of the following studies are being performed routinely, it is our goal to determine the relationship between serum HDL-cholesterol by multi-varied analysis with serum total cholesterol, triglycerides, uric acid, glucose, index of free thyroxin level, urea nitrogen, blood pressure, EKG, chest film, CBC and urinalysis. In addition, despite the pioneer efforts of Gulbrandsen et al in middle-aged and elderly Japanese males, there is a need for establishing normal values of HDL-cholesterol for our local population by age, sex and ethnic derivation. These studies are already in progress. Other effects need to be studied, e.g., the influence of exercise upon so-called 'normal' values (8-10% of our subscribers are estimated to be runners or joggers). Our system of medical care delivery affords us close followup of those patients who develop arteriosclerotic heart disease, permitting correlation of the serum HDL-cholesterol with the results of diagnostic studies, e.g., coronary angiography, treadmill EKG, serum enzyme and, in the event of fatal disease, by post-mortem examination.

SUPPORTED BY American Heart Assn. $11,000

2.0010,

CORONARY RISK FACTORS IN RUNNERS AND NON-RUNNERS

G.G. Rhoads, University of Hawaii System, Manoa Campus, School of Public Health, Dept. of Public Health Science, *Spalding Hall, Room 255, Honolulu, Hawaii* 96822

The purpose of this proposal is to compare selected lifestyle and physiologic characteristics between a random sample of marathon runners, other runners, and appropriate controls. Items to be evaluated by mail include height, weight, age, sex, ethnicity, education, occupation, alcohol and tobacco use, exercise habits, past medical history, and family history of coronary heart disease. Approximately 125 runners and 75 controls will be examined to obtain skinfolds, blood pressure, measured height and weight, and total and HDL cholesterol. Multivariate statistical techniques will be used to estimate the decrease in coronary disease incidence that might be expected in runners, based on differences in coronary risk factors.

SUPPORTED BY American Heart Assn. $10,000

2.0011,

FREQUENCY OF CLICK-MURMUR CHARACTERISTICS IN NORMALS

P.W. Willis, University of Michigan, Ann Arbor Campus, Medical School, Dept. of Internal Medicine, *1335 E. Catherine St., Ann Arbor, Michigan* 48104 (55-087-778)

The non-ejection systolic click and late systolic murmur syndrome has come to be recognized as a very common entity. There is disagreement about the prevalence of the auscultatory; phonocardiographic and echocardiographic characteristics of this syndrome among normal individuals. Studies thus far have shown prevalence rates of between .3% and 28% in healthy subjects depending on age and sex and method of detection. This project is designed to determine the prevalence of these findings among healthy young white men and women and to determine if individuals so affected are more often affected with chest pain, anxiety, arrhythmias, ECG changes at rest (T wave inversion in leads II, III, F, V5, V6) or ECG changes during or after exercise (RST segment depression or arrhythmia) than individuals from the same population who are free of the signs of the syndrome.

2.0012,

SERIAL EXERCISE TESTING IN HIGH RISK MALES

N.L. Lasser, College of Medicine & Dentistry of New Jersey, New Jersey Medical School, School of Medicine, Dept. of Medicine, *100 Bergen St., Newark, New Jersey* 07103

Although the submaximal graded exercise test (GXT) has become popular for the detection of preclinical ischemic heart disease, its predictive accuracy in asympatic subjects is low. The accuracy increases to 85% with serial testing, and the measurement of systolic time intervals (STI's) can greatly enhance predictive power. It is proposed to perform serial GXT's and pre-and post-exercise STI's at each annual examination of men participating in the Multiple Risk Factor Intervention Trial (MRFIT) in Newark. MRFIT, a multiple center collaborative Federally-sponsored clinical trial aimed at determining whether treatment of multiple risk factors (hypercholesterolemia, hypertension, smoking) reduces coronary mortality, is being carried out in 12,000 high-risk men, age 35-57, in control and experimental groups, with a 6 year follow-up. A baseline submaximal GXT was performed but will not be performed again as part of the national protocol. Continuation of GXT's at the Newark Center will be an ancillary study requiring outside funding. Tests will be carried out annually in the 632 men attending the Newark Clinic utilizing a Marquette Series 3500 Exercise System recording on paper and tape and an Irex Continu Trace 101 recorder, with computer analysis of the tapes. Analysis will be made of conversion rates of GXT's and changes in fitness levels. In addition to enhancing the power of the MRFIT these studies in this uniquely valuable population should demonstrate the ability to make the GXT a more accurate predictor of future coronary events and the potential use of the test as an endpoint in clinicial trials. These studies should indicate the utility of STI's as an adjunct to GXT and elucidate the effect of other lifestyle changes on exercise habits.

SUPPORTED BY American Heart Assn. $9,000

2.0013,

RELATIONSHIP OF BRONCHIOLITIS AND ASTHMA - A PROSPECTIVE STUDY

F.J. Twarog, Childrens Hospital Medical Center, Allergy Division, *300 Longwood Ave., Boston, Massachusetts* 02115

Bronchiolitis is an infectious disease of young children resulting in difficulty in breathing and wheezing. It is usually caused by a viral infection. It has been recognized that up to 50% of children who have had an episode of bronchiolitis go on to have recurrent attacks of wheezing and some develop asthma. Investigators have found that white blood cells from individuals with asthma have different characteristics than those of normal individuals. The purpose of this study is to determine whether children with bronchiolitis have similar abnormalities of their blood cells or whether those that subsequently develop asthma acquire this abnormality. If such a marker can be identified, it will be useful in studying the natural history and epidemiology of these diseases and for studying therapy and preventing asthma.

CENTRAL CANCER REGISTRY

N.J. Gray, Anti Cancer Council of Victoria, *90 Jolimont St., East Melbourne, Victoria 3002, Australia* (D-IARC-78-17)

The Central Cancer Registry continually monitors hospital data from large hospitals in Victoria, covering an estimated 50% of cancers occurring. Clinical data are recovered by medically qualified registry personnel and follow-up to provide survival data is rigorous. The registry yields information on relative frequency as well as treatment trends and results, and is available as a case-identifying center for retrospective epidemiological studies. A population based registry is now being developed to register all cases of cancer within the State of Victoria to enable incidence and prevalence to be established. Registry data are made available to research workers on request and advice on statistical and epidemiological techniques is also given.

2.0015,

CONTINUATION OF DEMONSTRATION CANCER CONTROL PROGRAM IN INDUSTRY

C.H. Tamburro, University of Louisville, School of Medicine, Dept. of Community Health, *101 W. Chestnut, Louisville, Kentucky* 40202

OBJECTIVE: To assess data gathered from an NCI Cancer Control Project Contract NO1-CN-55212. 'Implementation and Assessment of a Demonstration Cancer Control Detection and Prevention Program in a Cohort of Industrial Workers'.

APPROACH: A cancer control demonstration project was implemented in Louisville after the discovery of hepatic angiosarcoma, a rare cancer, Among polyvinyl chloride workers. This cohort is still undergoing medical surveillance and data is being stored and analyzed. This ongoing project is currently assessing the data gathered from the medical surveillance of these workers. The data base provides for evaluation of individually ill employees, provides monitoring of screening compliance, provides subcohorts for special studies, provides secondary non-invasive epidemiological research studies and finally a base for design and sample size consideration for future investigative projects.

PROGRESS: The sensitivity and specificity of federally-required screening tests as well as others is being determined. Twenty-two chemicals besides vinyl chloride are undergoing scrutiny as to their potential for causing disease. High and low risk subgroups have also been identified as to non-malignant hepatic and splenic disease. Four major primary sites of cancer development in the chemical (industrial) environment are under study in addition to hepatic angiosarcoma: A) Lung cancer, particular large cell carcinoma, B) Bilateral pleural thickening and possible relationship to inadvertent asbestos exposure, C) Colon cancer and acrylonitrile exposure and D) Brain cancer and vinyl chloride exposure.

EPIDEMIOLOGY OF MALE BREAST CANCER

M.A. Rahim, Bangladesh Cancer Epidemiology Research Program, Research Coordinating Unit, *49 E. Azimpur Gov. Estate, Dacca 5, Bangladesh*

OBJECTIVE: It has been observed that male/female breast cancer is 1:19 in Bangladesh. This observation is being followed-up by case control studies of patients reported to the radiotherapy units and registered to the ad-hoc registry of BCERP. Questions are asked on family history, local irritation, local trauma, sexual characteristics, testis abnormalities, gynecomastias, liver function tests including liver biopsy, and 17-ketosteroid excretions are examined. Compilations of data are done at the Bangladesh Cancer Epidemiology Research Program Research Coordinating Unit.

2.0018,

CANCER EPIDEMIOLOGY RESEARCH PROGRAM (BCERP) - DATA ACQUISITION

M.A. Rahim, Bangladesh Cancer Epidemiology Research Program, Research Coordinating Unit, *49 E. Azimpur Gov. Estate, Dacca 5, Bangladesh*

OBJECTIVE: To study relative frequency of cancer, all sites, in hospital populations in Bangladesh.

APPROACH: The hospital facilities to treat cancer patients which are available have been included in the present study, but participation of the hospital is voluntary and some hospitals, therefore, have elected not to join the project. Consultants of the participating hospitals are co-investigators. After interview and examination of the patient a record is prepared

according to guide lines of WHO Hand Book for Standardized Cancer Registries. The records are sent to the Bangladesh Cancer Epidemiology Research Program Research Coordinating Unit for manual compilation and statistical analysis.

A STUDY OF EPIDEMIOLOGY, PATHOLOGY, CLINICAL MANAGEMENT AND OUTCOME OF MALIGNANT MELANOMA IN WESTERN AUSTRALIA

B.K. Armstrong, National Health & Medical Research Council, Research Unit in Epidemiology & Preventive Medicine, *Canberra, A.C.T., Australia*

All patients (about 500 expected) having pre-invasive or invasive malignant melanoma of the skin diagnosed in Western Australia in 1980 and 1981 will be included in a case-control study - and detailed review of histopathology and clinical management undertaken. The case-control study will include demographic features, details of sun exposure (particularly intermittent versus continuous), objective measures of solar skin damage, diet and other relevant habits. Controls will be matched by age and sex using the electoral roll as a sampling frame. All relevant prognostic features will be recorded in the histopathologic review, including Clark's level and tumor thickness. Melanoma patients will be followed for at least ten years to document prognosis in relation to histopathology and clinical management.

DIET AND BILE SALT METABOLISM IN THE AETIOLOGY OF COLON CANCER

W.M. Castleden, University of Western Australia, Queen Elizabeth II Medical Centre, Dept. of Surgery, *Nedlands, W. Australia 6009, Australia*

Dietary and metabolic epidemiological studies in humans, by us and others, have suggested that colon cancer development may be related to diet and/or bile salt metabolism.
OBJECTIVE: To examine the biliary and fecal bile salt concentrations in patients with adenocarcinoma of the large bowel, and to compare this with control patients, matched for age and sex.
APPROACH: A form of consent is obtained from all patients. The first specimen of feces passed by the patient after admission to hospital is collected and freeze-dried for fecal bile salt estimation. Bile is collected either by endoscopic retrograde cannulation of the bile duct or from patients at operation. Bile salts are estimated by gas chromatographic method.
PROGRESS: Studies are still in the developmental phase.

PROSPECTIVE CLINICAL STUDY OF PROGNOSTIC FACTORS IN PRIMARY AND RECURRENT COLORECTAL CANCER

L.H. Blumgart, University of Glasgow, Royal Infirmary, Dept. of Surgery, *84 Castle St., Glasgow G4 0SF, Scotland, United Kingdom* (SP1406-B)

OBJECTIVE: A detailed prospective study of clinical and pathological prognostic factors in patients with colorectal cancer.
APPROACH: All patients with large bowel cancer treated at a single center were prospectively studied. Detailed information on clinical presentation, relevant past history, operative findings and evidence of distant metastases were noted. Particular attention was paid to the extent of primary tumor spread. Patients have been followed at regular intervals postoperatively and precise data on survival and cause of death has been recorded.
PROGRESS: Local tumor invasion to involve adjacent organs or structures significantly decreases the 3-4 year survival pattern, as compared to patients with freely mobile tumors. This factor has been of more significance in this study than the tumor involvement of lymph nodes (Dukes' C1 tumors). The survival pattern of patients with liver metastases is related to the extent of liver involvement with tumor. Thus, patients with solitary liver metastases have a significantly improved survival compared to those with widespread metastases. The study of natural history and prognostic factors has defined those patients who would receive most benefit from adjuvant therapy.

BACTERIA AND THE ETIOLOGY OF CANCER

R. Williams, Central Public Health Lab., Bacterial Metabolism Research Laboratory, *Colindale Ave., London NW9 5DX, England, United Kingdom* (SP 1386)

OBJECTIVE: To study the role of bacterial metabolites of bile acids in the causation of large bowel cancer.
APPROACH: We have developed, over the last 5 years, a discriminant based on fecal analyses for bile acids and certain clostridia. We are testing the value of this discriminant prospectively in: (a) groups of patients at St. Mark's Hospital, London at high risk of developing bowel cancer and (b) healthy persons living in 3 areas of Britain recruited through their general practitioners.
PROGRESS: The groups of patients and healthy persons have been recruited to the study. It is too early in the study to report on the results.

THE RELATIONSHIP OF LOWER RESPIRATORY TRACT DISEASE IN INFANCY TO THE DEVELOPMENT OF CHRONIC LUNG DISEASE IN ADULTS (ABBREV)

C.B. Hall, University of Rochester, School of Medicine & Dentistry, Dept. of Pediatrics & Medicine, *601 Elmwood Ave., Rochester, New York* 14627 (1164R1)

Bronchiolitis due to respiratory syncytial virus is the most important cause of mortality and morbidity in the first year of life. Evidence has been accumulating, suggesting that long-term sequelae in the form of chronic obstructive pulmonary disease in adult life, has its origins in respiratory illness during infancy. We are studying several populations of children in order to construct a long-term follow-up of the effects of lower respiratory tract disease in infancy.

PULMONARY FUNCTION TESTS IN ADOLESCENTS AND THEIR PARENTS - AN EPIDEMIOLOGICAL APPROACH

B.J. van den Berg, University of California, Berkeley Campus, School of Public Health, Dept. of Social & Administrative Health Sciences, *Berkeley, California* 94720 (1171R1)

This is a continuation of an epidemiologic study, whose main objectives are to increase knowledge of the determinants and correlates of spirometric measurements of pulmonary function in adolescents and to evaluate the importance of these measurements to predict chronic adult pulmonary disease. The following studies are proposed: 1) Establishment of norms of ventilation capacity for 15- to 17-year old adolescents; 2) Investigation of medical, biologic and environmental factors in relation to ventilation capacity; 3) Evaluation of familial patterns of basic parameters of pulmonary function in siblings, and adolescent-parent sets; 4) Analysis of the frequencies of medically attended acute and chronic diseases of the respiratory system in infancy, early and late childhood in our study population; and 5) To compare the data under 3) with the parents' smoking habits as well as with the adolescent's smoking habits. The 2400 adolescents selected for these studies are a subgroup of the study population of the Child Health and Development Studies.

EFFECT OF SMOKING ON EVOLUTION OF THE MAXIMUM EXPIRATORY FLOW-VOLUME CURVE

P. Hamosh, Georgetown University, School of Medicine, Dept. of Physiology & Biophysics/Medicine, *3800 Reservoir Rd. N.W., Washington, District of Columbia* 20007 (1108 R1)

The primary aim of this study is to obtain the MEFV curve three consecutive years in adolescents 12-14 years of age and relate the analysis of the curve to smoking habits and respiratory symptoms. The latter will be obtained by questionnaire.
Since the MEFV curve shows major abnormalities by the time subjects present themselves with respiratory complaints due to chronic bronchitis and emphysema, it is essential to identify early the 'susceptible.'
The secondary aim of this research is to identify a number of subjects who develop MEFV changes more severely or rapidly after starting smoking and follow this select group over an extended period of time.

STATISTICAL-GENETIC EVALUATION OF RISK FACTORS IN LUNG CANCER

H.T. Lynch, Creighton University, School of Medicine, Dept. of Preventive Medicine, *629 N. 27th St., Omaha, Nebraska* 68131 (941AR2)

We have designed an investigation which should enable the identification of risk factors in lung cancer with specific relevance to genotype-environmental interaction. This will involve an investigation of a large cohort (150 probands and their relatives) from Lynch, Nebraska (Holt County) and adjacent residential areas wherein a very homogeneous environmental setting (rural-farming) exists. Detailed family histories and smoking histories with emphasis upon first degree relatives have been obtained. Correlation between smoking history and cancer clustering, considering all histologic varieties, has been the prime objective of this study. This has lately involved assistance from the Nebraska State Department of Vital Records so that accurate information relevant to dates of birth and death could be compiled. This now includes cancer information on 7,558 individuals and smoking histories and information on chronic lung disease for probands and their first degree relatives (2,921 individuals). Incidence data from the state of Iowa will be utilized for appropriate comparison with the data from Holt County, Nebraska (inclusive of Lynch, Nebraska).
Analyses have considered only two-way associations between the phenotypes of cancer, smoking behavior, and chronic obstructive pulmonary disease (COPD). Familial factors to date have been studied with respect to cancer incidence. It will be advantageous to study familial clustering of COPD in a manner analogous to our model applied to cancer clustering. Impeding this effort is the lack of incidence for COPD comparable to cancer incidence surveys which exist nationally. At the present time, we are examining various ways to circumvent this problem. Should this prove feasible, we will then be able to examine familial clustering of COPD in families of smokers and families of nonsmokers to study this association within families. It may also then be possible to search for genetic association between COPD and cancer by consideration of the clustering of both phenotypes within families.

GLUCOCORTICOID HORMONE RESISTANCE IN THE LYMPHOCYTES OF INDIVIDUALS WITH ALLERGIES AND CYSTIC FIBROSIS

C.W. Distelhorst, Children's Hospital, *561 S. 17th St., Livingston Pike, Columbus, Ohio* 43205

The objective of this study is to test the hypothesis, resulting from our preliminary studies that glucocorticoid resistance is an inherited biochemical defect in the lymphocytes of a subset of individuals with allergic disorders. A possible relationship of this observation to cystic fibrosis is suggested by epidemiologic evidence that there is an increased incidence of respiratory allergy in cystic fibrosis patients and their families, and by biochemical evidence that the fibroblasts from patients with cystic fibrosis are resistant to the cytotoxic effect of glucocorticoids. Lymphocytes from allergic individuals and patients with cystic fibrosis will be tested for glucocorticoid resistance using a highly sensitive assay system. Family members will be studied in order to determine the role of heredity in the glucocorticoid resistance observed. The mechanism of glucocorticoid resistance will be determined by a detailed investigation of glucocorticoid receptor function in sensitive and resistant lymphocytes. It is expected that these studies will result in an improved understanding of the basic pathophysiology of allergic disorders and/or cystic fibrosis and could lead to more innovative forms of therapy.

ALCOHOL USE/ABSTINENCE AMONG MEN AND WOMEN IN A SMALL TOWN SETTING

E. Harburg, University of Michigan, Ann Arbor Campus, School of Liberal Arts, Dept. of Psychology, *Ann Arbor, Michigan* 48104

The general aims of this inquiry are to explore (through analyses of data already collected) the use, abuse, and nonuse of alcohol among men and women in a small town setting. The data concern drinking styles and histories, drinking behavior, temperament measures, life-stress, reasons for use and nonuse of alcohol, and recall of early family relations. The specific aim is to isolate some strong findings and prepare a paper and article.

The data come from a questionnaire survey of 2,273 persons who had been censused in a prior long-term medical study. The final sample of 1,683 persons represents 74% of those who completed and returned their questionnaire in 1977. The sample is about half men and half women. It includes four (overlapping) subsamples: (1) 183 husband-wife pairs (N=366 persons); (2) 314 sibling pairs (N=628 persons); (3) persons with alcohol and medical data from 1960-1962 (N=700 persons); and (4) persons with blood type data from 1965 (N=466 persons).

We will describe separately by sex and age for each of the four subsamples all the 539 variables and selected medical data and relate each variable to alcohol usage, i.e., amount of ethanol usage per week or category of usage. For the husband-wife and sibling subsamples, matched pair analysis will be used; for the other subsamples of individuals, basic regression or analyses of cavariance will be used. Human subject rights will be maintained.

This study should contribute to knowledge about women's use, abuse, and nonuse of alcohol which at present in spite of many years of research still seems in short supply. It is hoped such knowledge will be useful for educational purposes and therapy.

EPIDEMIOLOGY OF OROPHARYNGEAL CANCER, AND ESOPHAGUS AND BREAST CANCERS

D.D. Patel, Gujarat Cancer & Research Inst., Dept. of Surgery, *New Civil Hosp. Campus Asarwa, Ahmedabad 380016, Gujarat, India*

DESCRIPTION: Oropharyngeal cancer constitutes 45% of all cancers in men. Cancer of the base of the tongue is the most common form of this cancer. The exact etiology of such high prevalence of these cancers is still unknown.

Cancer of the esophagus constitutes 6% of all cancers in men. Etiological factors causing such high prevalence are still elusive.

Cancer of the breast constitutes 20% of all cancers in females. It is thought that its incidence is higher in Bohra community, a sect of muslims.

By collecting data on epidemiology it is desired to obtain some sensitive data to throw light on etiology.

PATHOLOGY OF BREAST TUMORS IN THE GUERNSEY PROSPECTIVE TRIAL

R. Millis, Imperial Cancer Research Fund, Breast Cancer Unit, *Lincolns Inn Field, c/o St. Bartholomew Hospital, London WC2A 3PX, England, United Kingdom* (311)

Review of breast cancers occurring in women who took part in the Guernsey prospective trial continues. Histological sections from all tumors developing in these women are examined and features which may be of prognostic significance evaluated. Particular note is made of the degree of inflammatory reaction, consisting mainly of lymphocytes and plasma cells, around and within the tumor, as preliminary studies have indicated that the degree of cellular reaction may be correlated with the levels of urinary aetiocholanolone in these women.

EPIDEMIOLOGY OF BREAST CANCER - EARLY ENDOCRINE EVENTS AND RISK

R.D. Bulbrook, Imperial Cancer Research Fund, Clinical Endocrinology Laboratory, *Lincolns Inn Field, c/o St. Bartholomew Hospital, London WC2A 3PX, England, United Kingdom* (26)

When the mean levels of plasma androgens, prolactin, progesterone and oestradiol were compared in adolescent girls with or without a family history of breast cancer, no clear differences were found (ICRF Scientific Report 1978-report 26). There is, however, tentative evidence that the inter-correlations between the various hormones differ in the two groups. For example, oestradiol and progesterone levels are highly correlated in the luteal phase in controls but not in the family history groups. It will be necessary to accumulate rather large numbers of subjects to investigate this point further.

FIBROUS CARCINOGENS IN TURKESTAN FLOUR

C.H. O'Neill, Imperial Cancer Research Fund, Anchorage Dependence Laboratory, *Lincolns Inn Field, c/o St. Bartholomew Hospital, London WC2A 3PX, England, United Kingdom* (161)

Esophageal cancer is a major cause of death in parts of Turkestan. The local distribution of the disease in this region, and its occurrence in certain other remote arid parts of the world, point to an environmental cause.

We have now been able to identify a sharply pointed silica fiber, about two hundred microns in length and three in diameter, as a common contaminant of the flour from this region. It is not present in European flour, or in flour from various villages in Turkey and Syria. It originates from the surface of the seed of a species of grass, Phalaris genus, which can readily be identified in the wheat because of its characteristic morphology. X-ray scattering distinguishes it from fibers of mineral origin such as asbestos and shows it to be pure silica. While we do not know how fibrous carcinogens act, we have in the past shown that they can stimulate the growth of cultured fibroblasts. Tissue culture experiments have now shown that Phalaris fibrils similarly cause conspicuous and immediate stimulation of the proliferation of 3T3 cells in soft gel suspensions, ultimately resulting in the production of large colonies.

During the course of the last year investigations in Iran have shown that 80 percent of the people in the affected areas suffer from esophageal dysplasia (leucoplakia). We have therefore instituted animal experiments to determine whether Phalaris fibers can cause similar dysplasia in mice, and whether they can promote the appearance of tumors initiated by chemicals. It is hoped that this work may eventually stimulate epidemiological testing of this hypothesis either in Iran or in the other affected regions (the Transkei and the area around Lin-Hsien in China).

EPIDEMIOLOGY OF BREAST CANCER - GUERNSEY PROSPECTIVE TRIALS 1961-1979

R.D. Bulbrook, Imperial Cancer Research Fund, Clinical Endocrinology Laboratory, *Lincolns Inn Field, c/o St. Bartholomew Hospital, London WC2A 3PX, England, United Kingdom* (23)

Blood and urine specimens have been obtained from 1,800 normal Guernsey women whose breasts were subsequently examined by mammography and palpation. Four radiological patterns of breast structure can be defined, which are thought to be correlated with various degrees of risk of breast cancer (although there is much controversy over this claim). We have found a highly significant correlation between the radiological patterns and several determinants of risk (such as age at birth of first child, parity, and use of contraceptive steroids). It follows, therefore, that the mammographic gradings are truly related to risk. The next step is to assay the blood

and urine specimens to see if particular endocrine profiles correlate with the radiographic patterns.

EPIDEMIOLOGY OF BREAST CANCER - PILOT STUDY OF ENDOCRINE RISK FACTORS IN A SCREENED AMERICAN POPULATION

R.D. Bulbrook, Imperial Cancer Research Fund, Clinical Endocrinology Laboratory, *Lincolns Inn Field, c/o St. Bartholomew Hospital, London WC2A 3PX, England, United Kingdom* (24)

Results from prospective studies in Guernsey (ICRF Scientific Report 1978-report 23) indicate that three endocrine abnormalities are associated with increased risk of breast cancer. These are a subnormal urinary excretion of androgens, a subnormal production of progesterone in the luteal phase of the menstrual cycle and an abnormally high level of plasma prolactin in the early hours of the evening. The results are tenuous and require confirmation and for this, a population of some 30,000 volunteers would be required. A pilot study has been started in New York in which the feasibility of obtaining blood from a screened population during the evening hours and of measuring, simultaneously, plasma androgens, progesterone and prolactin is being studied.

PATHOLOGY OF NORMAL AXILLARY LYMPH NODES FROM WOMEN IN GREAT BRITAIN AND JAPAN WHO DIED FROM CAUSES OTHER THAN BREAST CANCER (ABBREV)

J.L. Hayward, Imperial Cancer Research Fund, Breast Cancer Unit, *Lincolns Inn Field, c/o St. Bartholomew Hospital, London WC2A 3PX, England, United Kingdom* (306)

Comparative studies of the pathology of breast tumors and axillary lymph nodes from patients in Great Britain and Japan have shown that Japanese patients with early breast cancer have a higher incidence of sinus histiocytosis in the uninvolved axillary lymph nodes than patients in Great Britain. The incidence of sinus histiocytosis in axillary lymph nodes from British and Japanese women without breast cancer is now being investigated. In Great Britain lymph nodes obtained from coroner's post mortems performed on women who die suddenly without evidence of any malignant disease are being collected so that the degree of sinus histiocytosis can be assessed in histological sections. Similar nodes are being collected in Japan.

STUDY BY RIA AND RELATED TECHNIQUES OF SERUM ALPHA-FETOPROTEIN AND HEPATITIS B ANTIGEN IN ACUTE AND CHRONIC LIVER DISEASES IN GHANA

A.K. Foli, University of Ghana, School of Medicine, Medicine & Therapeutics, *P.O. Box 4236 Legon, Accra, Ghana* (1572/R1/RB)

OBJECTIVE: The objective of the project is: (1) To establish radioimmunoassay techniques for alpha-fetoprotein and Hepatitis B surface antigen in the country and use these facilities to (2) evaluate the diagnostic and prognostic significance of changes in alpha-fetoprotein level in patients with acute and chronic liver diseases as well as neoplasms, (3) to assess the importance of Hepatitis B virus in the aetiology of acute and chronic liver diseases as well as liver cancer in Ghana.

APPROACH: Normal serum values of alpha-fetoprotein are being established in the Ghanaian African. Changes in the protein level will be studied during the course of acute hepatitis, cirrhosis and primary cancer of the liver. The frequency of Hepatitis B surface antigen in the normal population will be evaluated. This antigen will be studied in the same group of people in which alphafetoprotein studies will be carried out and any correlation present will be assessed. Periodic, regulatory monitoring of alpha-fetoprotein and Hepatitis B antigen levels in asymptomatic antigen carriers as well as patients who have recovered from Hepatitis B virus infection will be pursued to determine the fate of these people with respect to the development of chronic liver disease and primary cancer of liver.

PROGRESS: Normal level of alpha-fetoprotein in the Ghanaian has been established as 10.2 ng/ml SD. 5.58. Transient rises of the protein occur in patients with hepatitis. The protein level was raised in 17% of 23 patients with cirrhosis and 83% of 30 patients with primary cancer of the liver. It was also raised in a small proportion with tumors having primary lesion in the sites other than liver.

CONTROLLED ASSESSMENT OF CURRENT AND PAST PSYCHOPATHOLOGY IN MEN WITH TESTICULAR TUMORS

J.G. Gorzynski, Memorial Sloan Kettering Cancer Center, Psychiatry & Solid Tumor Services, *1275 York Ave., New York, New York* 10021

OBJECTIVE AND APPROACH: Developmental history and current and past psychopathology are assessed in men with germ cell non-seminomatous tumors. Current and past psychopathology scales (CAPPS) are used for the assessment purposes. Age matched men with leukemia are used as a control group. The scale has eight areas of current and eighteen areas of past psychopathology. Preliminary results indicate a higher degree of past psychopathology, particularly among men with early life onset of testicular cancer.

Generally, they have poor social adaptation, low professional drive, frequent history of drug abuse, and delayed puberty. Endocrine evaluation of possible impairment of hypothalamic-pituitary-gonadal axis in men with testicular tumors is being planned.

INFANT MORTALITY, SOCIOECONOMIC AND RELATED CHARACTERISTICS: KANSAS COUNTIES-1975

D.J. Adamchak, Kansas State University, School of Arts & Sciences, Dept. of Sociology Anthropology & Social Work, *Anderson Hall, Manhattan, Kansas* 66502 (0013761)

OBJECTIVE: Measure the association between infant mortality, total mortality and socioeconomic and related characteristics in Kansas for the time period centering around 1975 in order to ascertain the nature of this traditional inverse relationship.

APPROACH: The research prodecure will utilize an ecological analysis, with the county of residence as the basic analytical unit. The independent indicators include functionsl county types (Capital intensive griculture, family farm, non-metropolitan manufacturing, servide center and metropolitan), demographic variables (age, population over 65 years of age, net migration, population density, percent rural-urban), family variables percent female head of houshold, marital instability), economic variables (several income variables including farm income, education variables, occupation variables), and housing, health, and medical, crime, and farm related variables. This structure will serve to discriminate counties and measure their overall health, social and economic well-being and thus serve to provide policy recommendations for disadvantaged counties by locating the particular type of indicator that is most sensitive to this relationship.

PROGRESS: In cooperation with the Ozarks Regional Commission, prepared a typology of Kansas counties related to their structure and function. Four major types emerged family farm, manufacturing, service and capital intensive farm. Pairs of counties of each type have been choosen, one which has had continuous out-migration since 1960 (called out-migration counties) and one which had out-migration between 1960 and 1970, but in-migration between 1970 and 1976. A ninth county, of the capital intensive farm type, had in-migration in both periods and will also be included. Contacts were made with community leaders and open meetings held in each county to get local input for the study, particularly in determine data they would feel would be useful on the questionnaire. Questionnaires were then sent out to pre-selected samples of in-migrant names, using local leades to trace down addresses. The results were then received, coded and analyzed. A meeting in each county was held to present the results and get local reaction. As of December, 1977, the process is underway in 7 of the 9 counties. It is completed in two of the counties, for which the final report is completed. (Text Truncated - Exceeds Capacity)

DIETARY PRACTICES AND CANCER RISKS

G. Bras, Rijskuniversiteit te Utrecht, Pathologisch Instituut, *Pasteurstraat 2, Utrecht, Netherlands* (UUKC PATH. 79-7)

OBJECTIVES: 1. To determine whether it is possible to predict early in life, which of the individuals permitted to select their own diets will develop tumors and which will not on the basis of their dietary practices. 2. To determine the extent to which the 'tumor inhibiting' dietary regiment voluntarily adopted by animals permitted freedom of choice will depress tumor incidence when that regimen is used as a guide for feeding animals that are generally tumor prone.

APPROACH: Our objective is to test the hypothesis that dietary practices early in life have a long-lasting effect on spontaneous tumor susceptibility. This hypothesis is based on data obtained from studies of rats permitted freedom of dietary choice. Rats that developed tumors differed in their dietary and growth behavior early in life from those that did not develop tumors. Additionally, there was a high degree of specificity between the dietary practices and tumor type. The conditions that characterize the pathological status of the individuals were expressed in the form of mathematical models comprised of multiple interacting factors; each factor representing a temporal-specific dietary or growth-related variable. The models will be used in two long-term experiments designed to test the hypothesis.

RELATIONSHIP OF DOSE AND EFFECT IN CARCINOGENESIS BY UV RADIATION

J.C. van der Leun, Rijskuniversiteit te Utrecht, Inst. of Dermatology, *Catharijnesingel 101, 3500 CG Utrecht, Netherlands* (UUKC D.77-6)

OBJECTIVE: The aim of this investigation is to find a correct description of the dose-response relationship in carcinogenesis by ultraviolet radiation. This will be used in the first instance for a better-founded estimation of the impact of a possible decrease in stratospheric ozone on the incidence of skin cancer.

APPROACH: Groups of albino hairless mice are exposed daily to the radiation from fluorescent sunlamps. Various groups of mice are given different daily doses of UV radiation; the doses given extend to lower, more realistic, values than in earlier investigations. The tumors formed are counted and examined histologically. By combining these and other experimental results with epidemiological data, an attempt is made to develop a consistent model for carcinogenesis by UV radiation.

PROGRESS: The first groups of mice have been under exposure since July 1, 1978. In the meantime we developed, on the basis of experimental and epidemiological data available, a theoretical relationship between dose and incidence of UV-induced skin cancers in human population. It yields an over-all amplification factor of 4, i.e., a decrease in stratospheric ozone of 1% would ultimately lead to an increase in skin cancer incidence of 4%.

CARCINOMA OF THE LARGE BOWEL AND DIETARY FIBER

M.L. Burr, Medical Research Council, Epidemiology Unit, *4 Richmond Rd., Cardiff CF2 3AS, Wales, United Kingdom*
OBJECTIVE: To investigate the possibility that a high intake of dietary fibre confers some protection against carcinoma of the large bowel.
APPROACH: About 10,000 subjects who are customers at Health Food shops, or who read health food journals, have been enlisted for this study. They have all completed a brief questionnaire which allows them to be classified into those who do and those who do not eat a high fiber diet. They can also be divided into meat-eaters, vegetarians, and vegans. Their National Health Service numbers have been obtained and notified to the NHS central registry, which informs us of deaths, with causes, as they occur in this population. Cancer registrations are similarly notified to us. Mortality and morbidity from large bowel cancer will be compared those in those on the high fiber diet and the rest, who will serve as controls. The effects of different kinds of dietary fiber and of vegetarianism will be examined separately.

2.0052,

LONG-TERM SURVEILLANCE OF MORTALITY AND CANCER INCIDENCE IN WOMEN RECEIVING HORMONE REPLACEMENT THERAPY

M.P. Vessey, University of Oxford, Dept. of Social & Community Medicine, *S. Parks Rd., Oxford OX2 6HE, England, United Kingdom* (G978/327)
OBJECTIVE: To detect any adverse (or beneficial) effects of hormone replacement therapy (HRT) on mortality and cancer incidence in perimenopausal and postmenopausal women. The use of HRT is on the increase in the United Kingdom and there is a need to monitor the long-term effects of such treatment. Concern about the long-term safety of HRT centers particularly around the fear that the risk of cancers of the breast, endometrium and ovary may be increased.
APPROACH: Women seen at menopause clinics in different parts of the country who (1) are currently using HRT and have been using it continuously for at least one year, or (2) are not currently using HRT, but used it in the past for six months or less, will be recruited and followed up indefinitely using the facilities of the National Health Service Registries. Mortality rates and cancer incidence rates experienced by the short-term and long-term users of HRT will be computed from time to time and comparisons will be made with national mortality and cancer incidence data. It is hoped that about 7,000 women will be recruited into the study prospectively and another 1,000 retrospectivey.
PROGRESS: Twenty-four menopause clinics have been visited and are now participating in the project; one more clinic will be visited shortly. A total of 1,200 women's records have been 'labelled' at the Central Registries.

LONGITUDINAL STUDIES IN ORAL LEUKOPLAKIA

J. Banoczy, Semmelweis Orvostudomanyi Egyetem, Conservative Dentistry Clinic, *Mikszath Kalman ter 5, 1088 Budapest V, Hungary*
670 patients with oral leukoplakia are under continuous control over a period from 1-30 years, with a mean observation period of 9.8 years. The objectives studied are: the frequency of malignant transformation, the distribution according to age, sex, localization and smoking habits, possible etiological factors and the conditions favoring malignant transformations. In the histological material of the same leukoplakia patients the frequencies of histological dysplasia and cancer as well as the ultrastructural characteristics are studied in correlation with the clinical types of leukoplakia.

INVESTIGATION OF SELECTED VEHICLE ACCIDENTS

D.F. Huelke, University of Michigan, Ann Arbor Campus, Inst. of Science & Technology, Highway Safety Research Institute, *Box 618, Ann Arbor, Michigan* 48104
Objective: To establish the mechanisms of trauma in motor vehicle collisions through intensive study of the relationship of occupant injuries to vehicle components, crash severity, and restraint system effectiveness. Significance: The emphasis of this continuing program is on establishing precisely how and why the injuries occurred and how they can be prevented or reduced. Methods: Approximately 130 collisions per year are selected from Washtenaw County crashes for detailed investigation. Only crashes with the following characteristics are selected: The crash has resulted in an injury; the vehicle (a late-model passenger car, pickup truck, van, recreational vehicle, or large truck) was manufactured by an MVMA-member company; the vehicle was towed away from the accident scene; and the vehicles involved can be examined within 48 hours of the collision. Results: Each clinical case is documented with the Collision Performance and Injury Report long form; detailed medical report; 35 mm color slides of the accident scene, vehicles, impacted object, exterior and interior damage; and reporting on other pertinent factors (alcohol, drugs, extrication complications, etc.).
SUPPORTED BY Motor Vehicle Manufacturers Assn. of the U.S. Inc. funds n.a.

2.0055,

CANCER INCIDENCE AND MORTALITY IN A COHORT OF RAILWAY EMPLOYEES

G.R. Howe, University of Toronto, Epidemiology Unit, *92 College St., Toronto, Ontario, Canada* M5S 1B2
OBJECTIVE: The study is designed to evaluate increased risk of cancer, particularly bladder cancer, in a cohort of railway employees classified by their occupation at time of retirement. This is a follow-up to an observation made in a previously reported case/control study of bladder cancer where increased risk was associated with exposure to fumes in railway workers.
APPROACH: Ex-employees of the Canadian National Railway alive at January 1, 1960 and who received a pension from the CNR form the cohort. The fact and data of death are on record and cause of death will be established using computerized record linkage to the national mortality data maintained by Statistics Canada. Cancer incidence amongst those alive as of January 1, 1969 will be determined using similar techniques with respect to the national cancer registry data (Statistics Canada). Comparisons will be made between those individuals whose occupations involve exposure to fumes and those whose occupations did not and also with Canadian population data.
PROGRESS: The basic records have been computerized and are currently ready for the linkage process.

2.0056,

AN ECOLOGICAL APPROACH TO ENVIRONMENTAL CANCER

R.A. Sonstegard, McMaster University, Dept. of Biology Pathology, *1200 Main St. W., Hamilton, Ontario, Canada* L8S 4L8
OBJECTIVE: Development of a system of monitoring tumor frequencies in feral fishes as a sentinel for the detection of environmental carcinogens. Initiate cohort epidemiological studies of 'heavy' fish-eaters in the Great Lakes basin.
APPROACH: Field epizootiological studies of fishes in the Great Lakes basin strongly link elevated tumor frequencies with extrinsic factors, possibly pollutants. Sports fishermen consume these fish(es) in quantity, and in light of their high xenobiotic burdens (they are banned from commercial sale), this represents an uncontrolled source of carcinogen exposure. In light of the same, feeding trials (feeding diets of fish which exhibit pathobiological response(s) which epizootiological studies link to extrinsic factors to laboratory rats and fishes) are being made with particular reference to health effects associated with dietary consumption of fish. The health responses recorded in these feeding trials will be incorporated (e.g., clinical chemistry) into the cohort epidemiological studies of heavy fish-eaters.

FOLLOW-UP OF BREAST CANCER CASES REPORTED BY NOVA SCOTIA SUBJECTS IN THE FLUOROSCOPY STUDY

G.R. Howe, National Cancer Inst. of Canada, Epidemiology Unit, *121 St. Joseph St., Toronto, Ontario, Canada* M5S 2R9
OBJECTIVE: The study is designed to determine whether any particular risk factors show synergism with respect to radiation in the induction of breast cancer.
APPROACH: This is a case-control study, the cases being those females identified as having developed breast cancer following institutionalization for tuberculosis in Nova Scotia between 1930 and 1952. Controls are being selected from the corresponding group who have not developed breast cancer. A substantial proportion of subjects have received considerable radiation exposure from fluoroscopy used in conjunction with artificial pneumothorax. All subjects are being personally interviewed in their own homes by a single interviewer to ascertain known risk factors for breast cancer other than radiation. The information so obtained will be combined with radiation exposure data obtained in an ongoing cohort project in order to evaluate any synergistic effect which may exist between radiation and other risk factors.
PROGRESS: The majority of respondents have been traced and a number of interviews completed.

MONITORING THE OCCUPATIONAL ENVIRONMENT FOR CARCINOGENS - A PILOT STUDY IN MONTREAL

J. Siemiatycki, Armand Frappier Institut, Centre de recherche en epidemiologie et medecine preventive, *531 Blvd. des Prairies, Case Postale 100, Laval des Rapides, Quebec, Canada* H7N 4Z3
Of the thousands of chemicals in the occupational environment, only a score have at present been demonstrated to be human carcinogens. There is no human evidence one way or another for almost all of the others. The very large number of agents renders inadequate conventional 'one-factor-at-a-time' epide-

miologic study methods (case-control or cohort). The objective is to establish an ongoing monitoring system capable of scanning the occupational environment to detect hitherto unsuspected human carcinogens. A case-control type methodology will be used. Cases will be adult male cancer patients hospitalized in the Montreal region. Several sites will be included and each will be analyzed separately. In the pilot study, controls for each site will be selected from the cases with cancer of other sites. For each man we will ascertain a lifetime history of exposure to a large number of agents. An innovative approach will be developed to ascertain occupational exposures which the worker might not be able to report or recall. This will be based on a self-administered questionnaire followed by an in-depth interview and research on the part of chemists and engineers with a view to inferring a list of possible chemical exposures associated with each job. This research will be based on technical documentation and consultation with a network of experts in various industrial sectors. The analyses will aim to identify high risk chemicals and workplaces. A two-year feasibility study will evaluate diverse aspects such as case ascertainment, data collection methods, and the statistical sensitivity of the system, before a long-term system is established.

2.0059,
THE EFFECT OF HYSTERECTOMY ON MORTALITY FROM CANCER OF THE CERVIX
A.B. Miller, National Cancer Inst. of Canada, Epidemiology Unit, Dept. of Preventive Medicine & Biostatics, *121 St. Joseph St., Toronto, Ontario, Canada* M5S 2R9
OBJECTIVE: To attempt to correct the effect of hysterectomy on mortality rates from cancer of the uterus for province by province data in Canada.
APPROACH: Previous work on mortality from cancer of the uterus (Int. J. of Cancer, 17, 602-672, 1976) did not include the effect of hysterectomy in the study population. Hysterectomies carried out for benign conditions would remove women from being at risk for cervical cancer and thus might explain the previously observed decline in mortality due to this disease. The current project will study this by repeating the analysis on national data in a province by province study.
On collaboration with Statistics Canada, data on the numbers of hysterectomies by one year age groups for women of ages 27-64, tabulated by province, will be used to estimate the number of women removed from being at risk. The available data will cover the period from 1969-1974. Thus, year by year the known population at risk in each age group can be adjusted to 'uteri at risk' instead of 'women at risk'. Using these corrected populations for the denominator, the mortality rates due to cervical cancer will be calculated on a province by province basis.
PROGRESS: The hospital morbidity data base of Statistics Canada is being used to produce initial tabulations of hysterectomies. Use of this data in the analysis of national cervical cancer data is expected to start in mid 1979.
SUPPORTED BY National Cancer Inst. of Canada funds n.a.

2.0060,
EPIDEMIOLOGICAL STUDY OF LARYNX CANCER
A.B. Miller, National Cancer Inst. of Canada, Epidemiology Unit, *121 St. Joseph St., Toronto, Ontario, Canada* M5S 2R9
OBJECTIVE: The study is designed to investigate the relative contribution of the known and suspected aetiological factors in laryngeal carcinoma. A prime focus of the study is on evaluating possible occupational causes, specifically asbestos exposure but also possibly other occupational factors such as exposure to nickel and nickel manufacturing processes. The study also investigates the relative contribution of smoking and alcohol consumption together with other factors to the development of laryngeal cancer.
APPROACH: The study is a case/control study with data on past events and exposures obtained from cases and controls by means of a detailed questionnaire. The study population consists of all newly diagnosed (as of March 1, 1977) cases with carcinoma of the larynx together with controls matched to cases by age, sex, and area of residence. All cases resident in southern Ontario together with those living in the Sudbury and North Bay areas are eligible for interview. Case acquisition will continue from March 1, 1977 through February 28, 1979.
PROGRESS: The study is currently in the second year of case identification and interview and after fourteen months of fieldwork a total of 130 case/control pairs have been interviewed. All questionnaires have been coded and have been entered on the NCIC Unit's computer for analysis.

2.0061,
HERPESVIRUSES AND CERVICAL CANCER
W.E. Rawls, McMaster University, Dept. of Pathology, *1200 Main St. W., Hamilton, Ontario, Canada* L8S 4L8
OBJECTIVE: The purpose of the study is to evaluate the role of herpes simplex virus type 2 (HSV-2) in the genesis of cervical carcinoma.
APPROACH: Previous seroepidemiologic studies have demonstrated an excess of antibody activity to HSV-2 among women with cervical carcinoma when compared to control women. However, the degree of association between antibodies to the virus and cervical cancer varies in different populations studied. To better define the meaning of the association, radioimmunoassay for HSV-2 type-specific antibodies will be used to analyze sera from a series of women with carcinoma of the cervix and from control women.
PROGRESS: A series of about 450 serum samples have been collected from women with cervical cancer and control women. Analyses of the samples for antibody activity to HSV-1 and HSV-2 are under way.

CASE CONTROL STUDY OF THE POSSIBLE ASSOCIATION OF MULTIPLE SCLEROSIS AND PETS
R.F. Kibler, Emory University, School of Medicine, Dept. of Neurology, *1364 Clifton Rd. N.E., Atlanta, Georgia* 30322
In a case control study we plan to look at the possible association between multiple sclerosis and pets, especially dogs. Pet ownership, characteristics of the exposure to the pet, some characteristics of life style, socio-economic status, places of residence and job history will be determined by interviewing patients with MS and two sets of controls, a neighborhood control and a clinic control. Through a review of medical records and interview we will establish the clinical status of the patient at the time of the interview, the date of onset of MS, and the clinical course. The pet history in both cases and controls will be corroborated by interviewing a family member or friend. Serum samples of patients and clinic controls will be tested for measles and canine distemper virus (CDV) antibodies by neutralization and complement fixation tests. The study results will be analyzed by matched pair analysis.

2.0063,
MULTIPLE SCLEROSIS IN THE FAEROES
J.F. Kurtzke, Georgetown University, School of Medicine, Dept. of Neurology, *3800 Reservoir Rd. N.W., Washington, District of Columbia* 20007 (RG 1191-A-5)
Survey of the Faroes in 1974, 1975 and 1977, and record review in 1976 by the authors led to the finding that 24 clinically definite MS cases among resident native Faroese had developed their first symptoms between 1943 and 1960. One born in 1950 had onset in 1970. Four cases of MS were excluded for prolonged foreign residence, and five for birth in Denmark. Otherwise there are known MS cases in Faroese. The 24 cases comprise a single cohort of the affected with a median year of onset in 1949. Their occurrence may be considered to constitute an epidemic, whose origin may possibly have been British troops (or their baggage) during the military occupation of the Faroese on the islands. Patient residences then matched well those currently known for the British forces.
Because of the critical importance of these findings in our understanding of MS, efforts will be made to accomplish (1) identification of the specific British troop units in question with manning levels, dates, and locations, (2) serologic evaluations and HLA-testing of MS and control households, (3) epidemiologic questionnaire of MS and control households, (4) ongoing neurologic surveillance of the islands (5) investigation of time-course of known diseases and deaths in the Faroes, (6) investigation of environmental changes in the Faroes (7) population sample questionnaires and serology.

2.0064,
THE GENETIC CONTROL AND THE REGULATION OF THE IMMUNE RESPONSE IN EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS AND MULTIPLE SCLEROSIS
M.J. Moore, Boston University, School of Medicine, Dept. of Neurology, *80 E. Concord St., Boston, Massachusetts* 02215 (RG 897-B-2)
Multiple sclerosis is a demyelinating disease affecting the central nervous system, primarily of young adults. It is a common disease which affects one in 2000 persons. Epidemiological studies have indicated that there is a higher risk of MS among family members of MS patients, but strict genetic inheritance has not been proven. Recent work has shown some correlation between susceptibility to MS and histocompatibility type as determined both by serological and mixed lymphocyte techniques. An experimental disease termed experimental allergic encephalomyelitis, EAE, has long been studied as a possible model for the human disease, MS. Using inbred populations of rats, we have recently shown that susceptibility to EAE depends in part on the presence of an autosomal dominant immune response gene, Ir-EAE, which is linked to the major histocompatibility locus of this species. When the genes of EAE susceptible and resistant rat strains are mixed by appropriate cross breeding, susceptibility to EAE still depends on the presence of the Ir-EAE gene. But now there are other factors which modify the disease process so that the symptoms may be very mild, or absent, even in a genetically susceptible individual. This sort of incomplete expression of a disease process which is controlled by a histocompatibility linked gene and modified by other genes, is exactly what would be predicted for human diseases which may be controlled by histocompatibility linked immune response genes. The purpose of this project is to identify the factors in the human and experimental disease which determine susceptibility and the severity of clinical course. Data obtained from these studies may lead to a rational form of immunotherapy for multiple sclerosis.

EVALUATION OF ORGANIC COMPOUNDS WITH MUTAGENIC AND CARCINOGENIC PROPERTIES PRESENT IN DRINKING WATER
H.J. Kool, National Inst. for Water Supply, Chemical Biological Division, *Postbox 150, 2260AD Leidschendam, Netherlands* (RID 80-1)
In the last decade significant advances have been made in the area of the quantitative and qualitative analysis of organic compounds in drinking water. The increased possibilities of analytical techniques to measure organic constituents have led to the conclusion that the occurrence of these compounds in surface water and in drinking water may create health risks.
In this respect special attention is nowadays paid to those compounds which may cause irreversible changes of the body tissues and for which at this moment threshold limit values cannot be established on a scientific basis, the carcinogens and mutagens.
In the Netherlands a survey of the organic composition of drinking water has been carried out. This study revealed that in drinking water prepared from surface water organic compounds with carcinogenic and mutagenic properties could be detected. For this reason the National Institute for Water Supply (NIWS) started an epidemiological study relating cancer mortality with the presence of organic micropollutants in drinking water of 20 cities in The Netherlands. In connection with this epidemiological

study, a preliminary examination for the presence of mutagenic activity in drinking water or surface water was carried out (Ames test). Without using concentration techniques half of the tested samples from the Rhine river were found to have mutagenic activity. Mutagenic activity could be shown in some drinking water after concentrating the organic contaminants by a factor 3000. A further screening of the drinking water in 16 cities is scheduled for 1979/1980.

EVALUATION OF ALTERNATE STRATEGIES FOR CONTROL OF XEROPHTHALMIA (VITAMIN A DEFICIENCY) IN THE PHILIPPINES

M.C. Latham, Cornell University, Ithaca Campus, Agricultural Experiment Station, *Ithaca, New York* 14850 (0072127)

OBJECTIVE: Determine the extent of the problem of vitamin A deficiency in Cebu in the Philippines and evaluate the feasibility effectiveness and cost of alternate strategies for its control.

APPROACH: Twelve areas in four different ecological zones (two urban and two rural) are being studied. Clinical, biochemical and dietary information indicated the extent of the vitamin A problem. Three intervention strategies are being evaluated each in 4 locations. These include providing a high dose vitamin A capsule every six months to children, fortification of MSG with vitamin A, and a public health and horticulture intervention.

PROGRESS: In the initial phase of the project we investigated the prevalence and epidemiology of vitamin A deficiency in 12 locations on the island of Cebu in the Philippines. The second phase recently completed consisted of an evaluation of three different intervention strategies to control vitamin A deficiency. These were (a) a public health and horticulture intervention ('PHI'), (b) the provision of 200,000 IU of vitamin A to children every 6 months (the 'capsule intervention'), and (c) the fortification of monosodium glutamate with vitamin A ('MSG intervention'). Each intervention was evaluated in 4 different locations or barangays, 2 rural and 2 urban. There was a reduction in eye signs of vitamin A deficiency with all three interventions, but the MSG intervention was the only one which also associated with a significant rise in serum vitamin A levels. Fortification is now being evaluated in three whole provinces, namely Cebu, Marinduque and Nueva Viscaya. The significance of the project is that it is testing and leading to a program to control vitamin A deficiency, the major cause of childhood blindness in the Philippines and some other Asian countries.

THE EPIDEMIOLOGY OF VISCERAL LARVA MIGRANS

R.H. Cypess, Cornell University, Ithaca Campus, New York State College of Veterinary Medicine, *825 Veterinary Research Tower, Ithaca, New York* 14853 (0074936)

OBJECTIVE: Determine the validity and reliability of the ELISA in the diagnosis of acute VLM.

APPROACH: Measure prevalence of antibody in several populations of children by using cross-sectional analysis. These studies should enable us to assess the Public Health implications of environmental contamination with this nematode.

PROGRESS: Continued progress has been made in determining the prevalence of infection with Toxocara canis in a variety of populations and determining associated risk factors related to transmission of this disease. Descriptive studies have indicated that infection rates vary with age, sex, and geographic distribution of populations, that occupational exposure is not a signficant risk factor, that the enzyme-linked-immunoabsorbant assay (ELISA) for the detection of Toxocara antibody is highly significant and specific under field and clinical situations.

ULTRASTRUCTURAL STUDIES OF BENIGN AND MALIGNANT HUMAN THYROID TUMORS

J.V. Johannessen, Radiumhospitalet, Laboratory for Ultrastructural Pathology, *Montebello, Oslo 3, Norway*

OBJECTIVE: To determine whether we can separate the benign thyroid tumors derived from the follicular epithelium from the malignant ones, by using transmission and scanning electron microscopy in conjunction with morphometry and DNA flow cytophotometry.

APPROACH: I have, during the past 6 years, collected several hundred specimens from human thyroid tumors. Most of the specimens have been secured for histopathology, cytology, transmission electron microscopy, scanning electron microscopy as well as histochemistry and DNA flow cytophotometry. The investigation aims to clarify whether there are diagnostically useful differences in the benign and malignant follicular thyroid tumors, as a proper classification may sometimes be impossible by light microscopy when no metastases are present.

The investigation furthermore aims to determine whether the follicular areas of papillary thyroid carcinomas are similar to follicular carcinomas or papillary ones, to determine whether the classification into mixed follicular and papillary carcinomas of the thyroid should be sustained or omitted. This not only has prognostic implications but also epidemiological ones, as some investigators now classify mixed tumors as such, while others classify them as papillary carcinomas, while still others classify follicular tumors with ground glass nuclei as papillary carcinomas.

PROGRESS: The work on the material has already started and preliminary results been published.

IDENTIFICATION AND CHARACTERIZATION OF HUMAN HISTOCOMPATIBILITY ANTIGENS - ASSOCIATIONS BETWEEN HISTOCOMPATIBILITY ANTIGENS/MALIGNANT DISEASES

E. Thorsby, National Hospital of Norway, Tissue Typing Laboratory, *Oslo 1, Norway*

OBJECTIVE: To characterize human histocompatibility antigens on normal and malignant cells; to study associations between histocompatibility antigens and certain malignant diseases on a population level, as well as associations between normal histocompatibility antigens and tumor-specific antigens in the cell membrane.

APPROACH: Antisera against human histocompatibility antigens were obtained by planned immunizations. Furthermore, to type for the HLA-D determinants, cells homozygous for HLA-D determinants were collected after studies of Norwegian families and the primed lymphocyte typing technique was established to identify these determinants. These reagents were then used to identify histocompatibility antigens on several different normal as well as malignant cells. Furthermore, HLA typing has been performed on several different patient categories. We are currently studying the association which might exist in the cell membrane between certain normal histocompatibility antigens and possible tumor-specific/induced antigens.

PROGRESS: By means of these techniques we are able to type for approximately 50 different HLA determinants. Some of them are present on all normal as well as malignant cells (the HLA-A, -B and -C antigens), others (the HLA-D determinants) are present only on some cells (lymphocytes, epidermal cells, endothelial cells, macrophages and possibly sperms). Some of the HLA-D determinants appear also to be serologically detectable, and have been detected on B lymphocytes, macrophages and endothelial cells. They are also present on leukaemic cells, and typing for these determinants seems to make it possible to distinguish between acute lymphatic leukaemia of B and T cell origin. This has previously not been possible, and appears to have important prognostic value. Furthermore, an association between malignant melanoma and the HLA-D antigen LD 108 has been detected.

DETERMINATION OF TOBACCO SMOKE METABOLITES IN URINE AND BLOOD

I. Baksaas, Telemark Sentralsjukehus, Dept. of Occupational Medicine, *Olavsgt. 26, 3900 Porsgrunn, Norway*

OBJECTIVES: Phase I: To determine metabolites of tobacco smoke in urine and blood. Phase II: Use of metabolite studies to identify indicators characteristic of individuals with high risk of cancer.

APPROACH: I) Metabolites are going to be determined in urine and blood of heavy smokers and non-smokers. The metabolites will be studied by gas chromatography with flame ionization/electron capture detector, high-pressure liquid chromatography with variable UV/fluorescence detector and by mass spectrometry. II) The same procedures are to be applied for screening of metabolites in already identified tobacco smoke-exposed population and industrial-exposed population.

EPIDEMIOLOGY OF CERVICAL DYSPLASIA

R.W. Morgan, University of Toronto, Dept. of Preventive Medicine & Biostatistics, *92 College St., Toronto, Ontario, Canada* M5S 1B2

OBJECTIVE: This project has two phases. Phase I encompasses the compilation and analysis of already existing data on approximately 1,800 patients seen at the Toronto General Hospital Dysplasia Clinic. This data will be used to generate hypotheses for Phase II, a case-control study designed to examine the relationship between cigarette smoking and dysplasia of the uterine cervix. Because of the recent evidence linking cigarette smoking and various types of cancer (including carcinoma of the uterine cervix) it is likely that exposure to cigarettes may also increase the risk of cervical dysplasia, a precursor to carcinoma of the uterine cervix.

APPROACH: Cases and controls will be drawn from three hospital clinics: the Dysplasia Clinic (cases), the Family Planning Clinic (controls), both from Toronto General Hospital, and the Dermatology Clinic (controls) from Women's College Hospital. Each case and control will be interviewed during regular clinic hours in the hospital. The questionnaire for the study will contain questions on demographic information (date of birth, education, income, race, marital status), smoking history, age at first intercourse, number of sexual partners, and obstetrical and gynecological history, and questions on contraceptive practices.

A SEROEPIDEMIOLOGIC STUDY OF ENDOGENOUS SEX HORMONES IN NEOPLASTIC DISEASE OF THE ENDOMETRIUM

C.A. Woolever, McMaster University, School of Medicine, Dept. of Obstetrics & Gynecology, *1200 Main St. W., Hamilton, Ontario, Canada* L8S 4J9 (367)

We will determine the serum concentration of sex hormones in three groups of women, i.e., those having a recent diagnosis of carcinoma of the endometrium, hyperplasia of the endometrium and no endometrial disease. Serum samples are obtained from women who have had a recent histologic diagnosis of these conditions, as well as from a control population of age-matched women living in the same neighborhood as the cases. The samples are being analyzed for androstenedione, estrone, estradiol, estriol and their conjugates. Intergroup comparisons will be made with respect to the presence and absence of recent disease and the use of exogenous estrogens. Sample collection will be completed in April 1979 and the analyses by the end of the grant year.

ASSOCIATION BETWEEN BENIGN AND MALIGNANT BREAST LESIONS

I.H. Soini, Tampere Yliopisto, Dept. of Public Health, *Vuolteenkatu 11, 33100 Tampere 10, Finland*

The objective of this study is to demonstrate a possible relationship between benign and malignant breast lesions using risk factor analysis of hormonal and reproductive data.

Epidemiological data were gathered from 600 women operated on for benign breast lesions be-

tween 1974 and 1977. The risk factors of benign and malignant lesions should also be related if there is a causal association between benign and malignant lesions or if they are associated without the transition of a benign lesion to breast cancer.

QUEENSLAND MELANOMA PROJECT
N.C. Davis, Princess Alexandra Hospital, Queensland Melanoma Project, *Ipswich Rd., Woolloongabba, Brisbane, Queensland 4102, Australia* (D-IARC-78-13)
The Queensland Melanoma Project has been in existence since July 1963. Between 1963 and 1969 every new case of malignant melanoma occurring in the state of Queensland was registered at the Princess Alexandra Hospital in Brisbane. All the microscopic diagnoses were confirmed by a panel of pathologists. We now have records of over 1500 patients whose clinical and pathological features have been recorded. These patients are being carefully followed up and form the basis of many papers on the epidemiology, clinical and pathological features, and biological aspects of melanoma.

ESTROGEN TREATMENT AND CANCER OF THE ENDOMETRIUM - A PROSPECTIVE EPIDEMIOLOGICAL STUDY
E.D. Johansson, Riksforeningen Mot Cancer, Dept. of Obstetrics & Gynecology, *Sturegatan 14, S11428 Stockholm, Sweden* (1291-B78-01XA)
The objective of this prospective follow-up survey is to investigate the supposed relationship between oestrogen treatment and endometrial carcinoma in climacteric women. The incidence of endometrial cancer in women treated with various oestrogens during an observation period of at least 5 years is studied and observed; incidence will be compared to that of non-exposed women. In Sweden the recorded crude incidence of endometrial cancer is approximately 40-50 per 100,000. To demonstrate a two-fold increase with statistical validity, it will be necessary to follow approximately 15,000 individuals. A special procedure has been set up to register all oestrogen-treated women through their prescription forms and collect data regarding their exposure. Approximately 18,000 women have been registered after 20 months of collection. All cases of endometrial cancer that occur during the observation period will be registered continually at the pathology departments of this region. To safeguard against losses due to migration, a final check in the national cancer register will be made. The oestrogen-exposed cases will be thoroughly examined for certain characteristics that are known to be linked to endometrial cancer, such as obesity, hypertension, diabetes, infertility, etc. The distribution of these characteristics will be compared to that of non-exposed cancer cases, exposed women without cancer and 'healthy' women of corresponding ages.

STATISTICAL STUDIES OF SURVIVAL DEPENDING ON DIFFERENT CANCER SITES, ESPECIALLY BREAST CANCER IN WOMEN
B. Mattsson, Radiumhemmet, Oncologic Centre, *S10401 Stockholm, Sweden* (750-B77-05X)
Breast cancer is the most common form of cancer in women. A remarkable increase in the number of registered cases in the Regional Cancer Registry of Stockholm has been noted during the last decades. This increase in incidence can not be explained only by a change in the age-distribution of the population. The mortality trends do not show the same increase. This project aims to study the incidence and survival trends in female breast cancer in the Stockholm region.
The increasing discrepancy between incidence and mortality figures will be studied with the view of elucidating whether it is real or not. The observed discrepancy might for instance be explained by prolonged survival time. By studying cancer registry breast cancer material from 1961-1963 and from 1971-1973 the survival times will be compared.
The explanation for the increasing number of breast cancer cases could be: a) changing diagnostic criteria; b) earlier diagnosis; c) increased diagnostic efforts; d) more frequent reports to the registry; and e) a real biological increase in incidence.
All these factors will be studied in relation to incidence and mortality trends.

GEOGRAPHIC INCIDENCE STUDIES ON CANCER MORTALITY AND CANCER MORBIDITY IN NORTHERN SWEDEN
L. Larsson, University Hospital of Umea, Center of Oncology, *S90185 Umea, Sweden* (1046-B78-04XA)
With data from the Swedish cancer registry age-adjusted incidence rates have been calculated for all communes in the three most northern counties in Sweden for the period 1959-71. Significant differences between the communes have been observed for several cancer types, such as male lung cancer, female breast cancer and malignant lymphomas, probably caused by differences in environment and living habits. The material is at present supplemented by data about new cases reported from 1972-77. Case-control studies are performed as regards lung cancer and malignant lymphomas with special regard to environmental factors.

CHECKLIST AND TRAINING GUIDELINES FOR AGRICULTURAL WORKER SAFETY
D.L. Roberts, Clemson University, Agricultural Experiment Station, Dept. of Agricultural Engineering, *Long Hall, Clemson, South Carolina* 29631 (0072857)
OBJECTIVE: Develop a usable safety and health inspection checklist having a hazards hierarchy for S.C. Agricultural Branch Experiment Stations and a modified version for the agricultural producer. Establish guidelines for agricultural employee training in high-potential accident job functions.
APPROACH: Define ag worker annual job functions at ag exp stations; index jobs' potential for serious acci; develop hazards hierarchy checklist on basis of indexing to include items based on characteristics of 72-76 worker injury reports, NSC survey statistics of farm acci, OSHA requirements, etc.; compile & establish guidelines for ag employee training for safe & healthful job performance; test checklist & use training guidelines at ag exp stations & modify for ag producer.
PROGRESS: Six years of injury reports (785) were analyzed for South Carolina Agricultural Experiment Station workers. Partial findings support the statement that nearly all such injuries can be prevented through improved worker training and worker's subscription to correct work procedures and use of personal protective equipment. Preliminary descriptions of agricultural job functions according to their potential for producing serious accidents or health hazards. (Job's Hazards Hierarchy) coupled with characteristics of the 785 accidental injuries and other agricultural accident data indicate areas where improved and increased training would be beneficial. Most agricultural jobs have been rated to have very low potential for serious injury or health hazard. Jobs rated to have slight to high potential for serious injury/health hazard show most potential for beneficial worker training in 'risk assessment of jobs'.

EPIDEMIOLOGICAL EVALUATION OF HUMAN AND ANIMAL HEALTH AS ASSOCIATED WITH CONTAMINATED WELL WATER
A. Robinson, University of Minnesota, St. Paul Campus, School of Veterinary Medicine, Dept. of Large Animal Clinical Sciences, *256 Veterinary Science, St. Paul, Minnesota* 55101 (0077655)
OBJECTIVE: Determine the severity, frequency and magnitude of motality and morbidity in humans and animals consuming well water of various qualities. Estimate the economic impact of mortality and morbidity in humans and animals as a result of consumption of contaminated well water supplies. If needed, provide a description of the cost benefit ratio of implementing available methods to treat contaminated water or provide alternative sources of water, in cases where it has been indicated as the source of human and domestic animal illness.
APPROACH: Analyze the health of humans and domestic animals who obtain their water supply from wells of various construction and depths in the Karst topography of southeastern Minnesota. Approximately 20 farms will be included in the study. Farms presently participating in the School of Public Health Study to identify significant indicators of contamination will be utilized, including cohorts of humans and animals consuming a satisfactory quality of water, and those consuming an unsatisfactory quality of water.
PROGRESS:

SEQUELAE TO LEAD POISONING:
D.K. Goldberg, Cornell University, Ithaca Campus, New York State College of Veterinary Medicine, Diagnostic Laboratory, *825 Veterinary Research Tower, Ithaca, New York* 14853 (0078461)
OBJECTIVE: Determine if there are long-term consequences of increased lead absorption in children and evaluate the current criteria for treatment of lead over-exposed children.
APPROACH: Twins who are discordant in their histories of childhood lead exposures will be compared on a number of measures including intelligence, visual-motor coordination, hyperactivity, and school performance. Use of twins will provide control for environmental risk factors other than lead and for genetic and cultural factors which might otherwise lead to confounding in outcome measures. The population of twins will be obtained from the records on the New York City Bureau of Lead Poisoning Control. Premorbid conditions will be determined from birth records, hospital/doctors records, and from parental interviews.

ECOLOGY AND GENETIC STABILITY OF FOOD POISONING C. BOTULINUM AND C. PERFRINGENS

H.P. Riemann, University of California, Davis Campus, School of Veterinary Medicine, Dept. of Epidemiology & Preventive Medicine, *Davis, California* 95616 (0002606)

OBJECTIVE: Find the natural reservoirs of food-poisoning strains of C. perfringens and C. botulinum and obtain information as to how these reservoirs are maintained. Obtain information with respect to the genetic control of toxigenicity in these two organisms.

APPROACH: Survey of prevalence and possible causal factors of C. botulinum will be carried out in areas epidemic with respect to wild fowl botulism, ranches, and slaughter houses and data studied epidemiologically. Same for C. perfringens. Genetic transfer will be studied by application of adapted genetic techniques and use of toxigenic and non-toxic mutants with appropriate genetic markers. Special attempts will be made to look for incomplete toxins, i.e., serologically cross-reacting materials.

PROGRESS: A number of seagull sera from Alaska were tested for botulinum antitoxins with negative results. Otherwise, research activities have been very limited because of lack of funds. A grant proposal for ecology studies of C. botulinum has been submitted to USPH.

SUPPORTED BY U.S. Dept. of Agriculture, Cooperative Research Office, California funds n.a.

2.0086,

HUMAN-FACTORS ENGINEERING FOR SAFETY, COMFORT, AND PRODUCTIVITY OF WORKERS

M.S. Kaminaka, University of California, Davis Campus, Agricultural Experiment Station, Dept. of Agricultural Engineering, *Davis, California* 95616 (0067664)

OBJECTIVE: Study equipment, work practices, and work environment and identify unsafe, inefficient, and uncomfortable practices with the intent of improving worker productivity, safety, and comfort. Acquire information on the capabilities and limitations of workers for performing typical tasks in the agricultural industry. This information should include the effects of fatigue and boredom and should be measured in terms of both physiological and sociological responses. Develop methods for gathering and analyzing statistics on accidents in typical agricultural and agribusiness operations. Develop effective, efficient and economical noise attenuating techniques to reduce noise levels in canneries.

APPROACH: Noise level measurements will be made throughout several canneries and specific noise sources isolated to determine the magnitude of cannery noise levels and the physical and economical constraints of noise control that will be consistent with FDA sanitation regulations and the efficient operation of canneries. Currently available noise attenuation materials will be tested for their noise reduction characteristics. Cannery equipment will be modified as needed to reduce noise levels.

PROGRESS: Analysis of Agricultural Machinery Related Job Skills. Detailed skills analyses (as opposed to descriptive task analyses) of agricultural machinery related jobs are not now available. Such analyses could be used to develop appropriate training or apprenticeship programs, or to aid in the placement of farm workers in jobs which match their present skills. Present screening methods for job applicants tend to rely upon selecting applicants based upon characteristics which seem to be related to success on the specified job. The approach followed here was to analyze selected types of agricultural machinery in order to determine how machine functions dictate what skill are required to operate the machine. The eventual goal is to determine what these required skill are. The immediate question was, 'Can these skills be inventoried in this manners?' A taxonomy of human skills developed by E. Fleishman was used in the initial phase of this work. In cooperation with a local farmer, analyses were conducted with machine operators and other workers (e.g., sorters) involved with mechanical tomato harvesters, pepper harvesters, sunflower combines, and manual operations such as row-crop (Text Truncated - Exceeds Capacity)

SELECTED FACTORS AFFECTING THE CONSUMER USE PERFORMANCE OF FLAME RETARDANT FABRICS

H.R. Richards, Colorado State University, School of Home Economics, Dept. of Clothing & Textiles, *Fort Collins, Colorado* 80523 (0071924)

OBJECTIVE: Determine the effects of methods of construction, selection of accessaries, stitching and garment design on the fammability performance of fabrics and apparel. Evaluate the feasibility of developing a meaningful fire hazard index for fabrics and garment systems to help the consumer in making judgments before purchasing fabrics and garments.

APPROACH: Medium weight fabrics will be used including untreated and flameresistant cotton and untreated and flame-resistant 50:50 cotton-polyester. Similar lightweight fabrics will be tested, if the results on medium weight indicate the necessity. Flame-resistant #50 cotton or 50:50 cotton-polyester thread will be used for stitching the flame-resistant fabrics and accessories and untreated thread used for the untreated fabrics and accessories. Accessories will include zippers, velcro, buttons of different materials, buttonholes, and pockets. Construction methods will be by fusible-tape adhesion, high frequency adhesion, and three types of sewn seams. Constructed specimens will be tested by 3-second and 12-second exposures in the vertical flame test and the char length and residual flame time determined, as well as the residual strength where practical. Appropriate data from cooperating stations and other sources will be tested in experimental formulae to develop a Flammability Hazard Rating (FHR) for fibers or apparel. This should correlate with the frequency with which the fabric or garment is involved in burn injuries, taking into account the market share and frequency of use.

PROGRESS: The effect of heat on fabrics, yarns, and sewing thread was determined for temperatures from 125 degrees C to 180 degrees C and periods of from 4 to 120 hours. Fabrics included untreated and flame-retardant wool, cotton, and 70-30 polyester/cotton, and untreated polyester and nylon - a total of 12 fabrics was examined. Yarns and threads included yarns from each of the above-noted fabrics and other commercial untreated and flame-retardant cotton, polyester, and nylon threads - a total of 32 yarns. Each fabric was characterized according to structure, fabric count, and weight, and each yarn by tex, twist, and ply. Before and after heat treatment, the following properties were determined: yarn length and breaking strength, and fabric dimension (standard square), breaking (tensil (Text Truncated - Exceeds Capacity)

FUNGAL- AND ALGAL-INDUCED DISEASES IN ANIMALS AND MAN

P. Krogh, Purdue University, School of Veterinary Science & Medicine, Dept. of Veterinary Microbiology, *Life Sciences Bldg., West Lafayette, Indiana* 47907 (0076505)

OBJECTIVE: Elucidate the etiology of fungal- and algal induced diseases in animals; privide methods for detection of fungal and algal agents in feeds and foods; determine the health implications in man of fungal and algal agents.

APPROACH: Animal diseases will be experimentally induced by fungal and algal agents in order to determine the causal role of these agents. Field cases in animals and man of comparable diseases will be studied in order to elucidate the causal relationships.

PROGRESS: Since funds became available for this research project by September 21, 1978, equipment has been ordered to enable the conductance of the following investigations: Chemical determination of residues of ochratoxin A in human kidneys, by thin-layer chromatography. Taxonomic investigation of the ochratoxin-producing molds in ochratoxin-contaminated cereals from an area of endemic (Balkan) nephropathy. Laboratory production of algal toxins, including saxitoxin, gonya toxins, and anatoxiu. Development of chemical procedures for detection of algal toxins in foodstuffs and water.

DIETARY DISTRIBUTION AND METABOLIC FATE OF TRANS FATTY ACIDS

M. Keeney, University of Maryland, College Park Campus, Agricultural Experiment Station, Dept. of Dairy Science, *College Park, Maryland* 20740 (0079349)

OBJECTIVE: Determine fatty acid composition, particularly Trans-and Cis- acids in the American diet; alterations in membrane structure resulting from incorporating trans fatty acids; the transport of trans fatty acids into brain tissue; whether trans fatty acids are transported across placental membranes, and conduct an epidemiological study comparing intake of trans fatty acids by 3 groups with different risk of cancer.

APPROACH: By standard methods determine fatty acid content of dietary fats and oils. Evaluate lipid from many tissues of organs for mice fed control diets and diets high in trans fatty acids. Similar studies to 2 on brain tissue. Evaluate lipids in the fetuses from cattle and mice fed diets high in trans fatty acids. Evaluate kind of fat eaten by a Jewish (high risk) and Seventhe Day Adventist (SDA) (low risk), and a non-Jewish-non-SDA population (control). Compare trans fatty acid levels in these diets.

HUMAN FACTORS ENGINEERING

R.H. Wilkinson, Michigan State University, Agricultural Experiment Station, Dept. of Agricultural Engineering, *New Administration Bldg., East Lansing, Michigan* 48823 (0067899)

OBJECTIVE: Study the agricultural worker's performance, safety and comfort as affected by: machine vibrations, noise, dust, temperature, humidity and other environmental factors, machine controls, display location and operator position.

APPROACH: Field studies to determine health problems of agricultural workers. Develop vibration measuring capability for field studies of conditions, experienced by machine operators. Monitor body functions (i.e. heart rate, muscle tremor, etc.) as a measure of man's physical response to job demands, vibration, environment and work space. Modify a tractor cab to control and analyze environmental stress. Simulate work tasks to evaluate mental and physical performance. Evaluate shape coding of controls, location, movement, displays and operator position on performance. Evaluate performance in various milking parlor configurations.

PROGRESS: A graduate student project is underway to evaluate the effects of various levels of whole body vibration on operator response time and performance. An operators station has been constructed that can be vibrated with various amplitudes and frequencies. The operators performance on a tracking task will be studied with and without whole body vibration. Results are expected in 1979.

2.0091,

ELEMENTS OF NUTRITIONAL ANEMIA AMONG BLACKS IN CENTRAL MISSOURI, PHASE II

R.M. O'Neal, Lincoln University, School of Agriculture, Dept. of Agricultural & Natural Resources, *Jefferson City, Missouri* 65101 (0074830)

OBJECTIVE: Delineate the types and extent of the anemias associated with nutrient deficiencies, i.e., iron, folic acid and vitamin B(12). Relate the incidence and types of nutritional anemies to the food consumption patterns of the population groups. Relate socioeconomic characteristics of the population groups to the incidence of nutritional anemias and food consumption patterns.

APPROACH: Samples of participants from black population in Central Missouri will be determined. Blood samples, food recall history and socioeconomic records will be obtained. Blood will be checked for anemia and nutrients. The blood data and food intake will be examined for correlation.

PROGRESS: With 83% of the families interviewed, tested and the data in preliminary summation, we found that among women of child bearing age there was a direct relationship between weight and height ratios to elevation of blood pressure, and increased skinfold thickness to elevated blood pressure. There also seems to be a relationship between family income and dollars spent on food, as well as the family size in relationship to the family income. As

the size of the family increased the total income decreased and as this decreasd the average grocery dollar also decreased. A fairly extensive food preference list has been compiled to reflect the eating habits of Black families in Central Missouri. The dietary summary so far reflects 36% receiving L100% but -G67% of the RDA for iron and 19% receiving less than 67 but more than 50% for iron. There is no problem with dietary intake of B(12) as reflected in the biochemical data and in the case of folic acid there were 36% receiving less than 100% RDA but greater than 67% and 27% receiving less than 67% of their RDA but greater than 50% as is reflected in the biochemical data. Early summaries tend to point to iron and folic acid as being the ones in greatest need of attention since it has been shown that deficiencies do exist and should be corrected.

BURN INJURY STUDY: PRODUCT-RELATED BURN VICTIMS

J. Laughlin, University of Nebraska, Lincoln Campus, Agricultural Experiment Station, Dept. of Textiles & Clothing & Design, *Lincoln, Nebraska* 68508 (0079517)

OBJECTIVE: Determine the relationship of clothing-related and interior product-related burn injuries to various segments of the population in everyday living and working situations during a specified period of time for a well-defined population.

APPROACH: A questionnair, refined from the Nebraska Burn Study, will be sent to every hospital in Nebraska and will be completed from the medical records of inpatients by the hospital staff. The Nebraska Hospital Association endorsed the proposal for this project. Additional information will be obtained from data files of the Office of the State Fire Marshall. The questionnaire was designed to eliminate duplications in retrived data and eliminate outpatients, classify burn injuries, and identify factors which contribute to the accident. The total number of burn injuries and the number and characteristics of the clothing-related and interior product-related deaths and injuries for fiscal year (July-1, 1979 through June 30, 1980) will be determined for Nebraska. Statistical analysis will be developed as needed to utilize the information obtained from the questionnaire.

DETERMINANTS OF CONSUMER HEALTH STATUS IN THE NON-METROPOLITAN AREAS OF CENTRAL NEW YORK

P.S. Chi, Cornell University, Ithaca Campus, Agricultural Experiment Station, Dept. of Consumer Economics & Public Policy, *Ithaca, New York* 14850 (0074273)

OBJECTIVE: Collect micro-data on consumer health status and related information; assess health levels of certain groups within the non-metropolitan areas of Central New York; construct a multivariate model in which the key determinents of consumer health status will be ascertained; develop policy recommendation and publish research results.

APPROACH: A sample of 800 respondents will be randomly selected from the six non-metropolitan counties in Central New York. A mail-questionnaire will be the instrument for data collection. Techniques of cross-tabulation and standardization will be used to compare health levels among different social groups in the sample. Pathanalysis is the method for multivariate model construction.

PROGRESS: By September 1978, the literature review on consumer health staus was thoroughly completed with assistance of two computerized search systems: Social Science Citation Index and Sociological Abstracts. Decision was alllso made with regard to the measurement of consumer status. The sampling framework for the mai-questionnaire survey was established and the detailed structure of questionnaire was constructed. The next research step will be to pre-test the questionnaire instruments and to collect survey data. Since the investigator is on leave from September 1978 to August 1979, this research wi be resumed after he returns to Cornell.

THE QUALITY OF SEAFOOD CONSUMED BY THE PEOPLE OF SOUTH CAROLINA

A. Koli, South Carolina State College, School of Arts & Sciences, Dept. of Chemistry, *Orangeburg, South Carolina* 29115 (0073560)

OBJECTIVE: Determine mercury levels of Sea and Freshwater fish consumed by the people of South Carolina, determine the effect of fish species on the accumulation and distribution of mercury in their tissues, and compare levels of mercury found by geographic location and relate to environmental factors.

APPROACH: Determine the availability of knowledge on the quality of seafood consumed by the people of South Carolina. The fish samples will be collected from the Atlantic Coast of South Carolina for determination of mercury content. To accomplish this the state's coastline will be divided into 30 sections of ten miles apart. The fish samples will be frozen on dry ice and stored in a freezer. The fish tissue will be analyzed for mercury contents by flameless atomic absorption spectroscopy--Mercury Analyzer.

PROGRESS: A survey of mercury residues in saltwater fish from the Atlantic Coast of South Carolina was conducted to see if the problem of the magnitude of mercury contamination was evident in the South Carolina fisheries. Samples of fish and shellfish from the Atlantic Coast of South Carolina were collected during 1977 and 1978. The fish collected were Spot, Whitting, Silver Snapper, Flounder, Shrimp, Sea Bass, Squid, Grouper, Bluefish, Clam, Crab, Scallop, Speckled Trout, Opsanus Tau, Trinectes Maculatus, Stellifer Lauceolatus and Mullet. Mercury determinations were made on 75 fish samples collected from eight locations on the Atlantic Coast of South Carolina. Triplicate samples of fish tissue were analyzed by the wet digestion method. Digests were analyzed using flameless atomic absorption spectrophotometry procedures outlined by Hatch and Ott, and Uthe et. al as modified for use with a Perkin-Elmer, Colemena MAS-50 mercury analyzer. Different species vary in mercury content and larger fish contain higher concentrations of mercury than do smaller fish of the same species. All the fish analyzed contain mercury levels below the currently accepted guideline of 0.5 ppm. This means that fish from the Atlantic Coast of South Carolina are relatively clean and safe with respect to mercury for human consumption.

2.0096,

AN EPIDEMIOLOGICAL STUDY OF MENTAL HEALTH NEEDS OF RURAL COUNTIES IN TENNESSEE

B.A. Husaini, State University & Community College System of Tennessee, Tennessee State University, School of Arts & Sciences, Dept. of Sociology, *Nashville, Tennessee* 37203 (0070866)

OBJECTIVE: Determine the mental health needs and their specific etiological factors in the rural communities of Tennessee; determine the variation in both the needs and their etiology in relation to the demographic characteristics; determine the extent to which mental health services are utilized in the rural communities; determine the relationship between the demographic characteristics and both the use of mental health services and the degree of satisfaction with the services received; and develop model plants and services directed toward an effective resolution of mental health needs of the rural communities.

APPROACH: The study will use the survey method where individuals between the ages of 18 and 65 years will be interviewed for approximately an hour.

PROGRESS: Data regarding psychiatric symptomatology obtained from 713 residents of 9 rural Tennessee counties indicate that approximately 12% of the rural population may require some form of psychiatric services. Impairment was common among those of lower socioeconomic status, the divorced, widowed, or separated, females, and among older respondents. Further analyses indicated that apparent higher levels of symptomatology among blacks were due to the predominately lower socioeconomic states of black respondents. When the effect of physical health status is controlled, socioeconomic status differences diminish and impairment was more common among younger respondents. The occurrence of stressful life events was related to impairment--respondents reporting more life events manifested more psychiatric symptoms. Events most strongly related to impairment involved those regards as undesirable, unpredictable, and those for which social support was unavailable. Further analyses regarding the individual's internal resources (ego strength and locus of control) and external resources (social support) indicate that stressful life events exerted their greatest effect upon impairment in cases where both internal and external resource were minimal. Individuals with developed coping styles and well established social ties were strongly resistant to the effects of life stress. Service utilization in the rural community was quite limited--only 4% of respondents admitted to having sought psychiatric help.

ETIOLOGY AND EPIDEMIOLOGY OF MUSHROOMS COMPOST COMPETITORS

R.A. Calderone, Georgetown University, Graduate School, *3800 Reservoir Rd. N.W., Washington, District of Columbia* 20007 (0044593)

OBJECTIVE: Develop new and essential information about the causes and occurrence of mushroom compost competitors, and identify and evaluate specific fungi and actinomycetes as incitants of hypersensitivity pneumonitis (mushroom worker's lung) and make recommendations for control to mushroom growers.

APPROACH: Conduct a complete mycological investigation of the microbial flora of the mushroom growing media and atmosphere at various stages of crop preparation growth and clean-up to determine which specific organisms are responsible: Identify and culture fungi which cause pneumonitis reactions in mushroom workers. Extract and characterize antigens from these fungi which promote these reactions. Evaluate purified allergens as incitant of pneumonitis reactions using animal models. Elucidate commercial practices which control the condition.

PROGRESS: Frequently allergic respiratory diseases were contracted in the latter stages of mushroom culture and clean-out operation due to great spore loads from microbial flora occurring in mushroom compost. One hundred fifty-five organisms were isolated from these areas by means of spore traps and Anderson air samplers. The reactivity of 11 of the most frequently occurring organisms (9 fungi and 2 actinomycetes) was established using immunodiffusion and charcoal agglutination with sera obtained from both workers with alleged episodes of Mushroom Workers Lung Disease as well as workers with no recent episodes of disease. Six of 11 organisms isolated from mushroom beds showed reactivity with workers sera. Other fungi, actinomycetes, compost, and compost aerosols did not display reactivity. Although this data implies these organisms are responsible, no clinical proof of the disease has been obtained in any of the workers who claimed they were so affected. More organisms are being tested and more sensitive assays will be conducted to indicated which are causing the disease.

NATIONAL MICROCONSTITUENTS

H.L. Seagran, U.S. Dept. of Commerce, National Oceanic & Atmospheric Admin., National Marine Fisheries Service, Southeast Fisheries Center, *P.O. Box 12607, Charleston, South Carolina* 29412 (SEC-212)

Program will be national in scope and will address contaminant issues related to consumer safety. Will address chemical substances transferred from the environment to fish and fishery products at levels that may be harmful to the consumer. Management of this new program, separate from but augmenting existing regional contaminant/microconstituent activities, will be under a program manager, designated by SEFC, assisted by a NMFS National Board of Advisors and through consultation with industry nationally. Program will be organized into five (5) topics. These follow, together with the corresponding current year objectice(s) for each topic: (1) Contaminant surveys-improve methodology for trace lead levels in seafoods and implement a survey on PCB levels in selected inshore species suspected to accumulate organic contaminants; (2) Chemical form of specific contaminants-accelerate past-year NMFS research on mode of occurrence and chemical form of toxic cadmium residues in selected shellfish species, known to accumulate cadmium; (3) Toxicity of contaminants-accelerate past-year NMFS research on specific toxicity (to experimental animals) of cadmium naturally contained in seafoods and correlate/extrapolate to humans; (4) consumption surveys-complete application of earlier developed simulation model to determine probable intake by U.S. consumers of cadmium from dietary seafoods to assess relative risk; (5) Data management-develop system specifications for various users of a proposed national contaminant daia base. Contract activities will constitute the primary means by which this program will implemented. All the objectives and related current year activities summarized above will be carried out either by competitive contracts or by agreements with cooperating institutions.

24-HOUR MEAN PLASMA HORMONE LEVELS IN MEN WITH CORONARY HEART DISEASE

B. Zumoff, Montefiore Hospital & Medical Center, *111 E. 210th St., Bronx, New York* 10467 (DF051630)

AF FUNCTION-CORONARY HEART DISEASE IS A SERIOUS, WIDESPREAD MEDICAL AND PUBLIC HEALTH PROBLEM THAT IS OF PARTICULAR CONCERN TO THE USAF BECAUSE IT RESULTS IN THE LOSS OF MANY VIGOROUS AND RELATIVELY YOUTHFUL MEN FROM FLYING DUTIES AND OTHER MILITARY ASSIGNMENTS. THE AF HAS RECOGNIZED THE SERIOUSNESS AND MAGNITUDE OF THIS PROBLEM BY INSTITUTING BOTH RESEARCH STUDIES, SUCH AS THE LONG-TERM BLOOD LIPID FOLLOW-UP PROGRAM, AND CLINICALLY-ORIENTED LARGE-SCALE RISK MODIFICATION STUDIES, E.G. THE RECENTLY-APPROVED HEART (HEALTH EVALUATION AND RISK TABULATION) PROGRAM. THE RATIONALE FOR THESE STUDIES RESTS LARGELY ON THE PREMISE THAT COUNTERACTING OR MITIGATING THE KNOWN 'MAJOR RISK FACTORS' FOR CORONARY HEART DISEASE, NAMELY SMOKING, HYPERLIPIDEMIA AND HYPERTENSION, WOULD DIMINISH THE INCIDENCE AND PREVALENCE OF CORONARY HEART DISEASE IN USAF PERSONNEL. DEFICIENCY-EPIDEMIOLOGICAL STUDIES HAVE SHOWN THAT 'CLASSICAL' RISK FACTORS ACCOUNT IN THE AGGREGATE FOR ONLY ABOUT ONE-HALF OF THE INCIDENCE OF CORONARY HEART DISEASE IN HIGH-INCIDENCE POPULATIONS SUCH AS THAT OF THE UNITED STATES. THUS EVEN IF IT WERE POSSIBLE TO DECREASE ALL OF THESE FACTORS SIMULTANEOUSLY, AS THE USAF HEART PROGRAM PROPOSES TO ATTEMPT, AN EXCESSIVE INCIDENCE OF CORONARY HEART DISEASE WOULD REMAIN AS A SERIOUS HEALTH PROBLEM. IT APPEARS ESSENTIAL THEREFORE, TO DEVELOP NEW HYPOTHESES TO ACCOUNT FOR THE REMAINDER OF THIS EXCESS INCIDENCE OF CORONARY HEART DISEASE IN ORDER TO DEVISE APPROPRIATE METHODS FOR PREVENTION AND TREATMENT. OBJECTIVE-THE HYPOTHESIS UNDERLYING THIS RESEARCH IS THAT ABNORMALITIES OF THE ENDOCRINE ENVIRONMENT IN MAN PREDISPOSE TO THE DEVELOPMENT AND/OR PROGRESSION OF CORONARY HEART DISEASE. IF THIS IS SO, IT SHOULD BE POSSIBLE TO DEVELOP NEW AND EFFECTIVE PHARMACOLOGICAL THERAPY (WITH HORMONES, HORMONE METABOLITES, OR DRUGS CAPABLE OF ALTERING THE BLOOD LEVELS OF HORMONES OR HORMONE METABOLITES OR ANTAGONIZING THEIR EFFECTS) THAT COULD ACCOMPLISH BOTH PRIMARY AND SECONDARY PREVENTION OF MYOCARDIAL INFARCTION. HOW CONTRIBUTES-CONTRIBUTES DIRECTLY TO SUBAREA 1.5. PLANS ARE TO IDENTIFY WHATEVER DIFFERENCES IN PLASMA HORMONE CONCENTRATIONS THERE MAY BE BETWEEN MEN WITH AND WITHOUT CORONARY HEART DISEASE. TO ACHIEVE THIS, THE INVESTIGATORS WILL RIGOROUSLY DEFINE THE DISEASE-POSITIVE AND DISEASE-NEGATIVE POPULATIONS AND THEN CARRY OUT AN EXHAUSTIVE 'CROSS-SECTIONAL' COMPARISON OF THE HORMONAL STATUS OF THESE TWO POPULATIONS, USING A LARGE NUMBER OF PARAMET (TEXT TRUNCATED -EXCEEDS CAPACITY)

SUPPORTED BY U.S. Dept. of Defense, Air Force, Office of Scientific Research $45,500

THE EFFECT OF HIGH GZ FORCES ON SYMPATHETIC NERVOUS ACTIVITY

M.G. Ziegler, University of Texas, Medical Branch at Galveston, School of Medicine, Dept. of Pharmacology & Toxicology, *300 University Blvd., Galveston, Texas* 77550 (DF052300)

AF function - aircrew personnel operating high performance aircraft are exposed to increasing levels of rapid onset, sustained, repetitive maneuvering forces. It has been recognized that cardiovascular responses can be encountered which may be particularly important in determining performance and severely limit or restrict the capabilities of the aircrew. Deficiency - high performance combat aircraft are now capable of plus Gz forces in excess of those man can tolerate and still maintain consciousness. The primary physiologic means by which man tolerates plus Gz forces is through vasoconstriction and tachycardia regulated by sympathetic nervous activity. Recent animal studies indicate that high plus Gz forces may elicit sympathetic nervous activity so intense that it can cause cardiac lesions. Objective - the study is designed to measure the involvement of the sympathetic nervous system in man's response to high gravitational forces. Since norepinephrine is the neurotransmitter of the sympathetic nervous system, measurements of levels of plasma norepinephrine should provide a reliable index of sympathetic nervous activity. How research contributes - this research directly supports research and exploratory development on-going under Subarea 1.6, 'habitable crew environments in the Air Force operations' and ADM TP06, 'crew technology', respectively.

These experiments will determine the NE and DBH responses of men to stress and high plus Gz. The effect of duration and intensity of plus Gz on plasma NE will be measured and then some of these studies repeated with subjects wearing an anti-g-suit to see how effectively the suit decreases stress to the sympathetic nervous system. The M-1 maneuver is effective in increasing man's tolerance to high plus gz. Since muscular straining increases plasma NE, the M-1 maneuver may work partly through stimulation of sympathetic nervous activity. Plasma NE levels will be measured on subjects performing the M-1 maneuver to determine how effective a stimulus this is to sympathetic nervous activity. The levels of NE elicited by plus Gz and the M-1 maneuver will be compared with those elicited by exhaustive exercise.

USAFSAM RETURNED PRISONER OF WAR (RPW) DATA REPOSITORY

H.P. Wetzler, U.S. Dept. of Defense, Air Force, School of Aerospace Medicine, *Brooks Air Force Base, San Antonio, Texas* 78235 (DF322040)

TO ESTABLISH A SINGLE ARCHIVAL SOURCE OF CLINICAL DATA ON RETURNED PRISONERS OF WAR OF THE VIET NAM CONFLICT TO SUPPORT EPIDEMIOLOGICAL STUDIES AND TO PROVIDE A PERMANENT DATA BASE FOR FUTURE HEALTH CARE OF THE RPWS.

DATA TO BE ACQUIRED WILL INCLUDE ALL IN-PATIENT AND OUT-PATIENT CLINICAL RECORDS OF INITIAL RPW CLINICAL EVALUATIONS, ALL RADIOGRAPHIC STUDIES, ELECTROCARDIOGRAMS, ELECTROENCEPHALOGRAMS, RESULTS OF ANY OTHER SPECIALIZED PROCEDURES, THE DOD INITIAL MEDICAL EVALUATION FORM (IMEF), AND THE MEDICAL PORTION OF INTELLIGENCE BRIEFINGS. THE RESULTS OF ALL USAFSAM AEROMEDICAL EVALUATIONS ON RPWS WILL BE ADDED TO THIS DATA REPOSITORY. DATA WILL BE MICROFILMED FOR LONG- TERM STORAGE. SELECTED DATA ITEMS WILL BE COMPUTERIZED FOR STORAGE, RETRIEVAL, AND ANALYSIS.

TECHNIQUES FOR ASSESSING G-RELATED PATHOLOGY IN PILOTS OF HIGH-PERFORMANCE AIRCRAFT

E.B. Smith, Technology Inc., *16821 Buccaneer, Suite 206, Houston, Texas* 77058 (DF323760)

The myocardial infarctions that go unrecognized each year in the general population and the cardiomyopathy and subendocardial hemorrhage detected recently in swine exposed to acceleration stress make it imperative to develop a diagnostic tool to detect this damage if it exists in aircrew members of high-performance aircraft. An analytical biochemical technique that correlates with myocardial injury will be developed.

The experimental protocol of this task is divided into four parts: (1) select the most appropriate analytical method for serum creatine phosphokinase isoenzymes and other chemical indicators to validate myocardial injury, (2) correlate laboratory induced myocardial injury with these selected chemical indicators, (3) correlate myocardial damage resulting from plus GZ acceleration stress as in part 2, and (4) compare changes in isoenzymes concentrations in human subjects exposed to plus GZ acceleration.

2.0103,

G-RELATED PATHOLOGY IN AF PERSONNEL EXPOSED TO HIGH-G STRESS

K.K. Gillingham, U.S. Dept. of Defense, Air Force, School of Aerospace Medicine, *Brooks Air Force Base, San Antonio, Texas* 78235 (DF319710)

TO DETERMINE THE MAGNITUDE, DURATION AND OTHER PARAMETERS OF THE STRESS TO WHICH AIRCREW OF HIGH-PERFORMANCE FIGHTER/ ATTACK AIRCRAFT ARE EXPOSED DURING AERIAL COMBAT, AND TO DETERMINE THE PHYSIOLOGIC AND PATHOLOGIC RESPONSES TO THIS STRESS.

INFLIGHT RECORDINGS OF G STRESS, ECG, RESPIRATORY FLOW AND OTHER MEASUREMENTS WILL BE OBTAINED FROM PILOTS OF F-15, F-16, AND OTHER HIGH-PERFORMANCE AIRCRAFT DURING AIR COMBAT TRAINING. BLOOD AND URINE OF PILOTS AND HUMAN CENTRIFUGE RIDERS WILL BE QUANTITATIVELY ANALYZED FOR LEVELS OF CATECHLOAMINES AND OTHER STRESS HORMONES TO DETERMINE THE RELATIVE PHYSIOLOGIC AND BIOCHEMICAL EFFECTS OF DIFFERENT TYPES OF G STRESS.

HISTOLOGY & EPIDEMIOLOGY OF HODGKIN'S DISEASE

F.M. King, U.S. Dept. of Defense, Armed Forces Inst. of Pathology, *c/o Walter Reed Medical Ctr., Washington, District of Columbia* 20306

The purpose of this study is to examine 1,000 cases on a National Research Council (NRC) tape of which only 400 cases were located in the Institute. These cases are to be matched with an equal number of military men who did not come down with the disease, then by a computer analysis. Factors which appear unique to those who developed Hodgkin's disease are to be identified.

As a side study, the survival by cell type would also be evaluated through the computer after review of the histology, with a comparison study of pediatric cases.

Most of the 400 cases have been subclassified. (Some of the remaining cases which were first thought to be Hodgkins disease turned out to be either reactive lymph nodes, metastatic carcinoma, or rhabdomyoma sarcoma. Material was not available on some of the cases.)

A list of survivals, printed by the NRC computer is in the process of being compiled. We are also waiting for additional cases, possibly from the 600 cases which could not be located.

STATISTICAL CORRELATIONS OF CLINICAL, EPIDEMIOLOGIC & HISTOPATHOLOGIC INFORMATION ON LEPROSY PATIENTS FROM ZAIRE

W.M. Meyers, U.S. Dept. of Defense, Armed Forces Inst. of Pathology, *c/o Walter Reed Medical Ctr., Washington, District of Columbia* 20306

Clinical and histopathologic data have been coded and computerized. These data were derived from 1423 leprosy patients under treatment for leprosy at the Institut Medical Evangelique, Zaire. Biopsy specimens from 1123 of these patients have been studied at the Armed Forces Institute of Pathology.

The data from all patients have been analyzed, comparing age, sex, class of leprosy (clinical and histopathologic), lepromin reaction, blood groups and other parameters. The most important comparison thus far been between the clinical classification and the histopathologic classification of the 1123 patients. Using the Ridley-Jopling classification scheme, a six-group classification, we obtained 75 percent concordance between the clinical and histopathologic diagnoses. Ninety-eight percent of the diagnoses agreed within one step in the classification scheme.

Although this scheme of classification was proposed by Ridley and Jopling in 1966, it has never been tested. The results of our study thus far suggest that this classification scheme is practical and reliable. We are now using our sample of leprosy patients to test other parameters on which this classification scheme was based, i.e., the lepromin reaction (Mitsuda component), and bacillary population density.

STUDY OF ANTIBODIES AGAINST THE AGENT OF LEGIONNAIRES' DISEASE (LD)

W.M. Meyers, U.S. Dept. of Defense, Armed Forces Inst. of Pathology, *c/o Walter Reed Medical Ctr., Washington, District of Columbia* 20306

An explosive, common-source outbreak of pneumonia caused by a previously unrecognized bacterium primarily affected persons attending an American Legion convention in Philadelphia, Pennsylvania in July, 1976. Twenty-nine of the 182 cases were fatal. The disease has since been reported in at least 43 states of the U.S.A., in Canada, an in Europe, thus pointing to the wide distribution of the previously undiagnosed infection. By retrospective diagnosis on clinical and serological grounds other past outbreaks of LD have been discovered, such as: an epidemic in St. Elizabeth's Psychiatric Hospital in Washington, D.C. in 1965, an episode of acute febrile illness in the Pontiac, Michigan County Health Department in July, 1968, and an outbreak among members of the independent Order of Odd Fellows in Philadelphia in September, 1974. Results of serologic, cultural, and DNA relatedness studies have demonstrated that the LDB and an unclassified agent isolated in 1947 are the same species. Since the Philadelphia outbreak of Legionnaires' Disease in 1976, and to date, nine other outbreaks of Legionnaires' Disease have been reported to the Center for Disease Control (CDC) in Atlanta, Georgia involving a total of 558 cases of LD. Additionally, hundreds of sporadic cases of LD have been confirmed.

The recognition of any 'new' disease immediately raises the question of its impact on military preparedness. In the case of LD, the questions range from current prevalence to risk of exposure upon deployment. Specifically, we hope to learn whether clinical disease is limited to individuals who are medically compromised and whether exposure (as evidenced by seroconversion) can be predicted gecgraphically. We hope to learn the ratio of subclinical cases, and whether infection or exposure is occupation-related.

In addition, we hope to become experienced with diagnostic techniques, including both serologic and direct identification of the organism(s). There is sufficient evidence to suggest that, heretofore, different laboratories, using slightly different techniques, obtained radically different results. The proliferation of antigenically different strains of the organism (or at least recognition of the differences) suggests that the military would be well advised to not only remain abreast of the state-of-the-art but to attempt improvements.

Initially, antibod (Text Truncated - Exceeds Capacity)

SURVEY ANALYSIS OF ENVIRONMENTAL MEDICAL SYMPTONS AND RISK IN ARMY PERSONNEL

J.B. Sampson, U.S. Dept. of Defense, Army, Medical Research & Development Command, Research Inst. of Environmental Medicine, *Natick, Massachusetts* 01760 (DA0C6132)

THE NUMBER AND TYPE OF ARMY PERSONNEL WHO ARE SUBJECTED TO ENVIRONMENTALLY INDUCED ILLNESS AND INJURY ARE NOT AVAILABLE FROM THE CURRENT MEDICAL RECORDS SYSTEM. DATA ARE NEEDED ON THOSE EXPOSED AS WELL AS THOSE TREATED, ON PARTIALLY DISABLING SYMPTOMS WHICH MAY GO UNREPORTED, ON THE NATURE OF EXPOSURE (ESPECIALLY AS RELATED TO MOS DUTIES) AND ON MEDICAL RISK FACTORS DUE TO INDIVIDUAL BACKGROUND, PHYSICAL CONDITION AND HEALTH-RELATED BEHAVIORS. SUCH DATA, OBTAINED FROM AND PUBLISHED IN TERMS OF ACTUAL ARMY POPULATIONS, WILL BE VALUABLE IN FOCUSING RESEARCH, PROPHYLAXIS AND TRAINING. IT WILL BE OF DIRECT USE TO OPERATIONAL PLANNERS, FIELD COMMANDERS, AND POTENTIALLY EFFECTED INDIVIDUALS. AT THE END OF THE DEVELOPMENTAL PROCESS IT IS EXPECTED THAT THE PERFECTED SURVEY PROCEDURES WILL BE USED IN APPLIED WORK UNITS DEDICATED TO THE ANSWERING OF SPECIFIC QUESTIONS.

DEVELOP AND FIELD TEST SPECIFIC METHODOLOGY FOR DATA COLLECTION AND ANALYSIS FROM ARMY PERSONNEL WHO ARE EXPOSED TO CLIMATIC EXTREMES AND/OR SUSTAINED OPERATIONS DURING FIELD MANEUVERS, SPECIAL TRAINING, OR TRANSMERIDIAN DEPLOYMENTS AND TO RIGOROUS PHYSICAL FITNESS PROGRAMS. METHODOLOGY INCLUDES QUESTIONNAIRES, INTERVIEWS AND BEHAVIORAL OBSERVATIONS DESIGNED TO OBRAIN SUBJECTIVE AND OBJECTIVE DATA ON ILLNESS AND INJURY DURING FIELD OPERATIONS, AS WELL

AS RELEVANT BACKGROUND INFORMATION. THE METHODOLOGY WILL ALSO BE USED IN CONTROLLED LABORATORY EXPERIMENTS WHERE CLIMATIC CONDITIONS ARE MANIPULATED. SURVEY SAMPLING STATISTICS WILL BE APPLIED TO DETERMINE CONFIDENCE LEVEL IN THE OBTAINED SAMPLES. DEVELOPMENT INVOLVES TRAINING OF PERSONNEL AND THE DESIGN, PRETEST, SAMPLE TEST, REVISION AND VALIDATION OF THE SURVEY INSTRUMENTS. DATA OBTAINED WILL BE DESCRIBED IN TERMS OF PERCENT OR PERCENTILES IN SELECT ARMY SUBPOPULATIONS FOR EACH RELEVANT OR CLEARLY IDENTIFIABLE CLIMATIC CONDITION. WORK UNIT WILL CONSULT WITH MILPERC, OTSG'S PATIENT ADMINISTRATIVE DIVISION.

PREVENTION OF MILITARY ENVIRONMENTAL CASUALTIES BY EPIDEMIOLOGIC RESEARCH AND INFORMATION DISSEMINATION (22)

H.G. Dangerfield, U.S. Dept. of Defense, Army, Medical Research & Development Command, Research Inst. of Environmental Medicine, *Natick, Massachusetts* 01760 (DA0C6149)

IDENTIFY ENVIRONMENTAL MEDICINE PROBLEMS IN ARMY UNITS AS RESEARCH REQUIREMENTS. MAINTAIN DIALOGUE WITH DA STAFF AND LINE TO (A) COMMUNICATE RESEARCH RESULTS TO POTENTIAL USERS, (B) PROVIDE ASSISTANCE AND RESOLVE DIFFICULTIES IN INTERPRETING AND APPLYING RESEARCH, (C) IDENTIFY UNSOLVED PROBLEMS. PROVIDE A CONTINUING SOURCE OF IDENTIFIED, IN-DEPTH EXPERTISE ON THE IMPACT OF PHYSIOLOGICAL AND PSYCHOLOGICAL STATUS, MILITARY CLOTHING AND EQUIPMENT, NATURAL AND CREW COMPARTMENT ENVIRONMENTS, HIGH TERRESTRIAL ELEVATIONS, AND PHYSICAL FITNESS, ON THE SOLDIER S HEALTH AND MISSION CAPABILITY.

MAINTAIN DIRECT LIAISON WITH DA SCHOOLS, LINE AND STAFF UNITS BY VISITS, CONFERENCES, AND CORRESPONDENCE. MAINTAIN REFERENCE FILES ON CLIMATE, CLOTHING, AND EQUIPMENT, AND PHYSICAL AND PHYSIOLOGICAL DIFFERENCES AMONG MILITARY POPULATIONS, AS A BASE FOR PREDICTING ENVIRONMENTAL IMPACT AND MISSION CAPABILITY. ASSIST IN PREPARATION OF TRAINING FILMS, TB MEDS, FMS, AND OTHER DOCTRINE- PROVIDE CONSULTATION TO UNITS PLANNING MILITARY OPERATIONS UNDER STRESSFUL CONDITIONS- ASSIST WITH DOCTRINE FOR PHYSICAL TRAINING AND/OR ACCLIMATIZATION.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Research Inst. of Environmental Medicine funds n.a.

2.0124,

DEVELOPMENT OF SURVEY METHODOLOGY FOR ANALYSIS OF ENV MEDICAL SYMPTOMS AND RISK IN ARMY PERSONNEL

J.B. Sampson, U.S. Dept. of Defense, Army, Medical Research & Development Command, Research Inst. of Environmental Medicine, *Natick, Massachusetts* 01760 (DA0C6129)

THE NUMBER AND TYPE OF ARMY PERSONNEL WHO ARE SUBJECTED TO ENVIRONMENTALLY INDUCED ILLNESS AND INJURY ARE NOT AVAILABLE FROM THE CURRENT MEDICAL RECORDS SYSTEM. DATA ARE NEEDED ON THOSE EXPOSED AS WELL AS THOSE TREATED, ON PARTIALLY DISABLING SYMPTOMS WHICH MAY GO UNREPORTED, ON THE NATURE OF EXPOSURE (ESPECIALLY AS RELATED TO MOS DUTIES) AND ON MEDICAL RISK FACTORS DUE TO INDIVIDUAL BACKGROUND, PHYSICAL CONDITION AND HEALTH-RELATED BEHAVIORS. SUCH DATA, OBTAINED FROM AND PUBLISHED IN TERMS OF ACTUAL ARMY POPULATIONS, WILL BE VALUABLE IN FOCUSING RESEARCH, PROPHYLAXIS AND TRAINING. IT WILL BE OF DIRECT USE TO OPERATIONAL PLANNERS, FIELD COMMANDERS, AND POTENTIALLY EFFECTED INDIVIDUALS. AT THE END OF THE DEVELOPMENTAL PROCESS IT IS EXPECTED THAT THE PERFECTED SURVEY PROCEDURES WILL BE USED OR APPLIED TO WORK UNITS DEDICATED TO THE ANSWERING OF SPECIFIC QUESTIONS.

DEVELOP AND FIELD TEST SPECIFIC METHODOLOGY FOR DATA COLLECTION AND ANALYSIS FROM ARMY PERSONNEL WHO ARE EXPOSED TO CLIMATIC EXTREMES AND/OR SUSTAINED OPERATIONS DURING FIELD MANEUVERS, SPECIAL TRAINING, OR TRANSMERIDIAN DEPLOYMENTS AND TO RIGOROUS PHYSICAL FITNESS PROGRAMS. METHODOLOGY INCLUDES QUESTIONNAIRES, INTERVIEWS AND BEHAVIORAL OBSER-VATIONS DESIGNED TO OBTAIN SUBJECTIVE AND OBJECTIVE DATA ON ILLNESS AND INJURY DURING FIELD OPERATIONS, AS WELL AS RELEVANT BACKGROUND INFORMATION. THE METHODOLOGY WILL ALSO BE USED IN CONTROLLED LABORATORY EXPERIMENTS WHERE CLIMATIC CONDITIONS ARE MANIPULATED. SURVEY SAMPLING STATISTICS WILL BE APPLIED TO DETERMINE CONFIDENCE LEVEL IN THE OBTAINED SAMPLES. DEVELOPMENT INVOLVES TRAINING OF PERSONNEL AND THE DESIGN, PRETEST, SAMPLE TEST, REVISION AND VALIDATION OF THE SURVEY INSTRUMENTS. DATA OBNTAINED WILL BE DESCRIBED IN TERMS OF PERCENT OR PERCENTILES IN SELECT ARMY SUBPOPULATIONS FOR EACH RELEVANT OR CLEARLY IDENTIFIABLE CLIMATIC CONDITION. WORK UNIT WILL CONSULT WITH MILPERCEN, OTSG'S PATIENT ADMINISTRATIVE DIVISION.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Research Inst. of Environmental Medicine funds n.a.

2.0125,

INFECTIOUS MULTIPLE DRUG RESISTANCE IN ENTEROBACTRIACEAE

S. Falkow, University of Washington, School of Medicine, Dept. of Microbiology, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (DA0B7136)

TO DETERMINE THE GENTIC AND MOLECULAR ORIGIN(S) OF R-FACTORS AND OTHER GENETIC ELEMENTS OF ENTERIC ORGANISMS. TO FURTHER STUDY THE DETERMINANTS OF BACTERIAL VIRULENCE, THEIR EPIDEMIOLOGY, MODE-OF-ACTION AND OTHER FACTORS THAT CONTRIBUTE TO THE DEVELOPMENT OF RESISTANT STRAINS OF ORGANISMS KNOWN TO BE THE CAUSE OF MILITARILY RELEVANT OUTBREAKS OF DIARRHEAL DISEASES.

THE MOLECULAR NATURE AND MODE OF REPLICATION OF R-FACTORS IS TO BE INVESTIGATED. ALSO THE LOCATION OF AND METHOD OF TRANSFER OF THESE R-FACTORS BETWEEN DONOR STRAINS AND RECIPIENT STRAINS IS TO BE STUDIED.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research $46,198

2.0126,

THE ROLE OF NEWLY DISCOVERED EXOTOXIN (S TOXIN) IN PSEUDOMONAS AERUGINOSA INFECTIONS

B.H. Iglewski, Oregon State Higher Education System, University of Oregon Health Sciences Center, School of Medicine, Dept. of Microbiology & Immunology, *3181 S.W. Sam Jackson Park Rd., Portland, Oregon* 97201 (DA0J7581)

TO PURIFY AND CHARACTERIZE TOXIN FROM PSEUDOMONAS AERUGINOSA, AND ORGANISM FREQUENTLY INVOLVED IN INFECTIONS FOLLOWING BURNS OR BATTLEFIELD WOUNDS. SPECIFIC EFFORTS WILL BE CONCERNED WITH THE EPIDEMIOLOGY OF SUCH INFECTIONS AND THE PROTECTION OFFERED BY SPECIFIC ANTITOXIN. A LOGICAL OUTCOME OF THESE STUDIES WOULD BE THE DEVELOPMENT OF AN EFFICACIOUS VACCINE TO PROTECT WOUNDED AND/OR BURNED MILITARY PERSONNEL.

CONVENTIONAL EPIDEMIOLOGIC, BIOCHEMICAL AND SEROLOGICAL PROCEDURES WILL BE USED AND MODIFIED AS NEEDED.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research $51,494

2.0127,

MILITARY PSYCHIATRY EPIDEMIOLOGY

D.H. Marlowe, U.S. Dept. of Defense, Army, Medical Research & Development Command, Neuropsychiatry Div., *Washington, District of Columbia* 20012 (DA0C6454)

THIS UNIT EXAMINES MILITARY ORGANIZATIONAL, SOCIAL PSYCHOLOGICAL, AND ENVIRONMENTAL FACTORS THAT CREATE RISK FOR AND CONDUCE TO PSYCHIATRIC DISEASE, PSYCHOSOMATIC ILLNESS, BEHAVIORAL DYSFUNCTION AND PHYSICAL ILLNESS AS THEY EFFECT ARMY PERSONNEL AND IMPACT ON CARE GIVING AGENCIES.

THE METHODS OF EPIDEMIOLOGY, INCLUDING RECORDS SURVEILLANCE, POPULATION AND DEMOGRAPHIC ANALYSIS, QUESTIONNAIRE AND FIELD AND COHORT STUDIES AS WELL AS METHODS OF THE PSYCHOLOGICAL AND SOCIAL SCIENCES ARE USED TO DELINEATE ENVIRONMENTS OF RISK FOR PSYCHIATRIC ILLNESS AND PERIODS OF SPECIAL RISK FOR SUCH ILLNESSES AT CRITICAL POINTS IN THE CAREER OF THE SOLDIER.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0128,

MENINGOCOCCUS- BACTERIOLOGICAL, SEROLOGICAL AND EPIDEMIOLOGICAL STUDIES.

H.A. Feldman, State University of New York, Upstate Medical Center, School of Medicine, Dept. of Preventive Medicine, *766 Irving Ave., Syracuse, New York* 13210 (DA0A7318)

THIS STUDY INCLUDES DOCUMENTATION OF THE SULFONAMIDE RESISTANCE OF STRAINS OF MENINGOCOCCUS OBTAINED FROM ALL OVER THE WORLD, DEVELOPMENT OF ADEQUATE SEROLOGIC AND IMMUNOLOGIC METHODS FOR STUDY OF THESE INFECTIONS, THE STANDARDIZATION OF TECHNIQUES FOR USE IN COMPREHENSIVE STUDIES OF MENINGOCOCCAL INFECTIONS, AND A CONTINUING SEARCH FOR NEW DRUGS TO PROVIDE MASS CONTROL OF INFECTIONS. STUDIES OF THIS NATURE PROVIDE TO THE MILITARY THE ABILITY TO BETTER UNDERSTAND THE PATHOGENESIS OF MENINGOCOCCAL MENINGITIS, A DISEASE THAT HAS BEEN COMMONPLACE IN RECRUIT POPULATIONS.

APPROACH - STRAINS OF MENINGOCOCCI ARE OBTAINED FROM MILITARY AND CIVILIAN SOURCES WORLDWIDE. SEROLOGIC TYPING AND CONVENTIONAL ANTIBIOTIC TESTING ARE EMPLOYED. A CONTINUING SEARCH IS MAINTAINED FOR NEW DRUGS AND ANTIBIOTICS TO DETERMINE THEIR IN VITRO EFFECT UPON MENINGOCOCCI. ANY THAT APPEAR TO BE POTENTIALLY USEFUL ARE THEN EVALUATED FURTHER UP THROUGH THE LEVEL OF LIMITED FIELD TRIALS.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research $27,069

2.0129,

VECTORS AND NATURAL RESERVOIRS OF OROPOUCHE VIRUS IN THE AMAZON REGION

K.A. Western, Instituto Evandro Chagas, *Belem, Brazil* (DA0B7526)

CONDUCT EPIDEMIOLOGIC STUDIES OF INFECTIOUS DISEASES TRANSMITTED AMONG POPULATIONS ALONG THE TRANS-AMAZON HIGHWAY, WHICH ARE HIGHLY RELEVANT TO MILITARY MEDICINE AND WILL PROVIDE GUIDANCE FOR FUTURE RESEARCH PRIORITIES.

CONVENTIONAL PROCEDURES AND MODIFICATIONS WILL BE UTILIZED.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research $15,000

2.0130,

GENESIS OF ARTHROPOD-BORNE VIRAL EPIDEMICS

M.E. Wiebe, Cornell University, Medical Center, Cornell Medical College, Dept. of Microbiology, *1300 York Ave., New York, New York* 10021 (DA0C7272)

THE TECHNICAL OBJECTIVE IS TO TEST THE HYPOTHESIS THAT ENDEMIC OR SYLVATIC STRAINS OF VENEZULELAN ENCEPHALITIS VIRUS CONTAIN A MINORITY VARIANT WITH THE CAPACITY TO PRODUCE MAJOR EPIDEMICS. THERE IS A REQUIREMENT FOR RESEARCH WHICH CAN BE EXPECTED TO PROVIDE KNOWLEDGE ON WHICH TO FORECAST EPIDEMICS OF ARTHROPOD-BORNE VIRAL DISEASES WHICH PRESENT A HAZARD TO MILITARY PERSONNEL. THE APPROACH WILL BE TO SEPARATE THE VIRULENT SUBPOPULATION OF VIRUS FROM AVIRULENT STRAINS OF VIRUS BY THEIR PRESUMED DIFFERENTIAL ATTACHMENT PROPERTIES ON HYDROXYLAPATITE COLUMNS.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research $48,533

2.0131,

PARASITIC DISEASES OF MILITARY IMPORTANCE

D.E. Davidson, U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research, *Washington, District of Columbia* 20012 (DA0A6440)

TO STUDY PHYSIOLOGICAL, BIOCHEMICAL, PATHOLOGICAL AND EPIDEMIOLOGICAL ASPECTS OF PARASITIC DISEASES OF MILITARY IMPORTANCE. TO EVALUATE EXISTING TECHNIQUES AND TO DEVELOP NEW TECHNIQUES FOR DIAGNOSIS, PREVENTION, TREATMENT AND CONTROL.

CULTURE SYSTEMS AND ANIMAL MODELS OF PARASITIC DISEASES WILL BE DEVELOPED AND USED TO STUDY THE PARASITES OF INTEREST, THE PARASITIC DISEASE PROCESS, AND THE EFFECTIVENESS OF NEW DIAGNOSTIC, PREVENTIVE AND THERAPEUTIC MEASURES. STUDIES WILL EMPHASIZE BUT WILL NOT BE RESTRICTED TO MALARIA, LEISHMANIASIS, TRYPANOSOMIASIS, AND SCHISTOSOMIASIS.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0132,

VIRAL INFECTIONS OF MAN

W.H. Bancroft, U.S. Dept. of Defense, Army, Medical Research & Development Command, Communicable Disease & Immunology Research Div., *Washington, District of Columbia* 20012 (DA0A6441)

TO DEFINE ETIOLOGY OF ACUTE INFECTIOUS DISEASES OF SPECIAL HAZARD TO MILITARY PERSONNEL, TO DETERMINE AND EVALUATE FACTORS INFLUENCING OCCURRENCE, DISTRIBUTION, SEVERITY AND MEDICAL RESULT OF HUMAN VIRUS INFECTIONS, AND TO DEVELOP MEANS FOR REDUCING DISABILITY DUE TO VIRUS DISEASES.

CONTEMPORARY VIROLOGICAL AND IMMUNOLOGICAL METHODS ARE APPLIED TO DISEASE PROBLEMS OCCURRING IN TROOPS OR IN SUSCEPTIBLE CIVILIAN POPULATIONS IN STRATEGICALLY IMPORTANT AREAS. NEW CONCEPTUAL APPROACHES AND METHODS ARE DEVELOPED AS NEEDED FOR SPECIFIC PROBLEMS.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0133,

BACTERIAL DISEASES OF MILITARY IMPORTANCE

S.B. Formal, U.S. Dept. of Defense, Army, Medical Research & Development Command, Communicable Disease & Immunology Research Div., *Washington, District of Columbia* 20012 (DA0A6443)

STUDIES ON THE ETIOLOGY, ECOLOGY, EPIDEMIOLOGY, PATHOGENESIS, PHYSIOLOGICAL IMMUNOLOGICAL AND DIAGNOSITC ASPECTS OF DISEASES OF MICROBIAL ORIGIN WHICH ARE CURRENT OR POTENTIAL PROBLEMS TO MILITARY FORCES. CURRENT EMPHASIS ON CONTROL OF MENINGOCOCCAL, GONOCOCCAL, PSEUDOMONAS AND STAPHYLOCOCCAL INFECTIONS IN MILITARY FORCES.

DEVELOPMENT OF BACTERIOLOGIC TECHNIQUES FOR STUDY OF VARIOUS INFECTIOUS DISEASES. FIELD STUDIES ON PROPHYLACTIC REGIMENS, SPREAD AND PERSISTENCE OF ORGANISMS IN VARIOUS MILITARY POPULATIONS.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0134,

BIOLOGICAL STUDIES OF INSECT INFECTION AND DISEASE TRANSMISSION

D.J. Gould, U.S. Dept. of Defense, Army, Medical Research & Development Command, Communicable Disease & Immunology Research Div., *Washington, District of Columbia* 20012 (DA0A6514)

DEVELOPMENT OF PHYSIOLOGICAL MEANS OF INTERRUPTING MALARIA TRANSMISSION THROUGH AN UNDERSTANDING OF FACTORS AFFECTING PARASITE INFECTIVITY IN VIVO AND IN VITRO. DEVELOP TEST SYSTEMS FOR STUDYING MECHANISMS UNDERLYING SPOROZOITE INDUCED IMMUNITY FOR THE EVENTUAL PREVENTION AND CONTROL OF MALARIA IN MILITARY TROOPS. DEVELOP MODEL FOR THE TRANSMISSION OF AFRICAN TRYPANOSOMIASIS IN THE LABORATORY AND FOR UTILIZING THE PARASITES IN STUDIES INVOLVING THE IMMUNE RESPONSE.

DETERMINE QUANTITATIVELY SUCH PARAMETERS AS THE MINIMUM NUMBERS OF IMMUNE CELLS REQUIRED TO CONVEY PROTECTION AGAINST PLASMODIUM BERGHEI MALARIA. ISOLATION OF DIFFERENT STAGES OF THE MALARIA PARASITE ON DENSITY GRADIENTS FOR SUBSEQUENT STUDY IN CULTURE SYSTEMS. ESTABLISH A SELF SUSTAINING COLONY OF TSETSE FLIES FOLLOWED BY THE CYCLIC TRANSMISSION OF TRYPANOSOMES BETWEEN INSECT VECTOR AND RODENT HOST. SCREEN VARIOUS VERTEBRATE AND INVERTEBRATE CELL CULTURES FOR THE PROPAGATION AND DIFFERENTIATION OF THE BLOOD STAGHES AND INSECT CYCLE, RESPECTIVELY, OF TRYPANOSOMA RHODESIENSE.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0135,

EPIDEMIOLOGICAL STUDIES OF MILITARY DISEASES

O.C. Dobbs, U.S. Dept. of Defense, Army, Medical Research & Development Command, Preventive Medicine Div., *Washington, District of Columbia* 20012 (DA0B6489)

TO IDENTIFY, DEFINE, AND STUDY KNOWN AND POTENTIAL CAUSES OF DISABILITY IN MILITARY POPULATIONS USING RELEVANT, EXISTING UEPIDEMIOLOGIC TECHNIQUES AND DEVELOPING APPROPRIATE NEW METHODOLOGY. TO APPLY THIS INFORMATION TO THE PREVENTION AND CONTROL OF DISABILITY IN MILITARY POPULATIONS.

CONTEMPORARY EPIDEMIOLOGIC METHODS ARE APPLIED TO CAUSES OF DISABILITY IN MILITARY POPULATIONS. MULTIDISCIPLINARY COLLABORATIVE APPROACHES ARE UTILIZED AND NEW METHODS DEVELOPED AS REQUIRED.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0136,

MECHANISMS OF TRANSMISSION OF HEPATITIS VIRUSES

W.H. Bancroft, U.S. Dept. of Defense, Army, Medical Research & Development Command, Communicable Disease & Immunology Research Div., *Washington, District of Columbia* 20012 (DA0B6513)

TO DEFINE THE EPIDEMIOLOGY OF HEPATITIS IN MILITARY POPULATIONS IN ORDER TO ESTABLISH METHODS FOR REDUCING DISABILITY FROM HEPATITIS. EMPHASIS IS ON DEVELOPING AND APPLYING SENSITIVE AND SPECIFIC METHODS FOR DETECTION OF HEPATITIS VIRUSES/ANTIGENS AND ANTIBODIES TO DETERMINE HOST FACTORS IMPORTANT IN RESISTANCE TO DISEASE AND INFECTION IM MILITARY PERSONNEL.

NEW METHODS FOR IDENTIFICATION AND ANTIGENIC ANALYSIS OF HEPATITIS VIRUSES ARE UNDER DEVELOPMENT. THE IMMUNE RESPONSE OF PATIENTS INFECTED WITH HEPATITIS VIRUSES IS STUDIED TO DEFINE SENSITIVE PARAMETERS OF INFECTION AND TO DEFINE FACTORS CRITICAL IN IMMUNITY. THE EPIDEMIOLOGY OF HEPATITIS B IN MILITARY POPULATIONS IS DEFINED.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0137,

FIELD STUDIES OF RICKETTSIOSES AND OTHER TROPICAL DISEASES

D.L. Huxsoll, U.S. Dept. of Defense, Army, Medical Research & Development Command, Medical Research Unit, *Kuala Lumpur* (DA0B6526)

TO INVESTIGATE THE INCIDENCE OF SCRUB TYPHUS INFECTION IN SELECTED LOCAL AND FOREIGN POPULATIONS, TO RELATE THIS TO THE PREVALENCE OF VECTOR CHIGGERS AND THEIR COMMON RODENT HOSTS, TO DETERMINE THE STRAINS OF R. TSUTSUGAMUSHI CAUSING HUMAN INFECTIONS AND RELATE TO CLINICAL DISEASE, TO DEVELOP IMPROVED SEROLOGICAL METHODS, TO EVALUATE SIMPLE AND EFFECTIVE MEANS OF TREATMENT, TO STUDY THE BASIS FOR IMMUNITY, TO DEFINE VECTOR-RICKETTSIA RELATIONSHIPS, TO DEVELOP A LABORATORY ANIMAL MODEL FOR THE DISEASE, AND TO PRODUCE LABORATORY ANIMALS IN SUPPORT OF THE MISSION. SCRUB TYPHUS IS AN INCAPACITATING DISEASE OF MILITARY IMPORTANCE.

PROVIDES SCIENTIFIC REAGENTS AND EQUIPMENT WHICH CAN BE BEST PROCURED IN THE US FOR SHIPMENT TO AND USE BY WRAIR PERSONNEL IN MALAYSIA FUNCTIONING COLLABORATIVELY WITH MALAYSIAN SCIENTISTS SUPPORTED UNDER USAMRDC GRANT REPORTED ON DA 0A 7413.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0138,

FIELD STUDIES ON OROPOUCHE VIRUS

J.W. Leduc, U.S. Dept. of Defense, Army, Medical Research & Development Command, Medical Research Unit, *APO, Miami, Florida* 34030 (DA0B6528)

CONDUCT STUDIES ON THE ECOLOGY OF OROPOUCHE (ORO) VIRUS TRANSMISSION IN THE AMAZON BASIN IN COLLABORATION WITH THE EVANDRO CHAGAS INSTITUTE. THIS ARBOVIRUS IS THE MOST COMMON CAUSE OF ARBOVIRUS EPIDEMICS IN THE REGION AND COMMONLY RESULTS IN FEBRILE, DEBILITATING ILLNESS. INFORMATION ON THE DYV-DR ORO VE-Z

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0139,

TROPICAL AND SUBTROPICAL DISEASE IN MILITARY MEDICINE

H.E. Segal, U.S. Dept. of Defense, Army, Medical Research & Development Command, Medical Component, *Bangkok* (DA0C6465)

TO DEFINE THE ECOLOGY AND BASIC BIOLOGY OF CAUSAL AGENTS OF TROPICAL DISEASES, AND TO STUDY ENVIRONMENTAL VARIABLES THAT MAY AFFECT THE PERFORMANCE OF U.S. SERVICEMEN IN TROPICAL AREAS.

ROUTINE DIAGNOSTIC, EPIDEMIOLOGICAL, SEROLOGICAL, BIOCHEMICAL, MICROBIOLOGICAL, ENTOMOLOGICAL AND PSYCHOLOGICAL PROCEDURES ARE BEING UTILIZED. FIELD STUDIES ARE EMPHASIZED AND ARE SUPPLEMENTED BY APPROPRIATE LABORATORY INVESTIGATIONS.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0140,

MEDICAL FACTORS LIMITING SOLDIER EFFECTIVENESS

L. Ingraham, U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research, *Washington, District of Columbia* 20012 (DA0C6470)

TO IDENTIFY FACTORS IN THE MILITARY ORGANIZATIONAL, SOCIAL, PSYCHOLOGICAL AND PHYSICAL ENVIRONMENT THAT CREATE RISK FOR AND CONDUCE TO PSYCHIATRIC BREAK-

DOWN, BEHAVIORAL DYSFUNCTION, PSYCHOSOMATIC AND PHYSICAL ILLNESS AS THEY IMPACT ON INDIVIDUAL AND UNIT EFFECTIVENESS AND CONSUME HEALTH CARE RESOURCES.

THE METHODS OF EPIDEMIOLOGY, INCLUDING RECORDS ANALYSIS, POPULATION AND DEMOGRAPHIC ANALYSIS, QUESTIONNAIRE AND FIELD AND COHORT STUDIES AS WELL AS OBSERVATIONAL METHODS ARE EMPLOYED TO DEVELOP REQUISITE DATA.

SUPPORTED BY U.S. Dept. of Defense, Army, Medical Research & Development Command, Walter Reed Army Inst. of Research funds n.a.

2.0141,

STUDIES IN THE EPIDEMIOLOGY OF ARBOVIRAL INFECTIONS

G.T. Crane, U.S. Dept. of Defense, Army, Test & Evaluation Command, Environmental & Life Science Div., *Dugway Proving Ground, Dugway, Utah* 84022 (DA0K1535)

THE OBJECTIVE IS TO STUDY THE NATURAL INFECTION CHAIN FOR ARBORIRUSES OF WESTERN UTAH.

RABBIT SERA WILL BE COLLECTED AT SELECTED SITES IN WESTERN UTAH AND TESTED FOR ANTIBODIES AGAINST THE PREVALENT ARBORVIRUSES OF THE AREA. DATA GENERATED WILL BE USED TO ELUCIDATE NATURAL INFECTION CHAINS AND PARTICULARLY THE RESERVOIR SOURCES OF THE VIRUS- THIS WILL BE ANALYZED IN CONJUNCTION WITH PAST ACCUMULATED ARBORVIRUS DATA.

SUPPORTED BY U.S. Dept. of Defense, Army, Test & Evaluation Command funds n.a.

2.0142,

COLLECTION AND EVALUATION OF MEDICAL INFORMATION

T.J. Mason, U.S. Dept. of Defense, Defense Nuclear Agency, Armed Forces Radiobiology Research Inst., *Bethesda, Maryland* 20014 (DH090277)

TO OBTAIN AN HISTORICAL SUMMARY AND CENSUS OF PERSONNEL INVOLVED IN THE UNITED STATES ATMOSPHERIC NUCLEAR WEAPONS TESTING PROGRAM FROM 1945 THROUGH 1962. THIS SUMMARY IS TO BE USED FOR MEDICAL FOLLOW-UP EVALUATIONS TO DETERMINE THE RELATIONSHIP BETWEEN LOW DOSES OF IONIZING RADIATION AND DISEASES.

OBTAIN CUMULATIVE DATA FROM HISTORICAL DOCUMENTS TO COMPILE A COMPLETE HISTORICAL SUMMARY OF ALL ATMOSPHERIC NUCLEAR WEAPONS TESTS. THIS SUMMARY WILL CONTAIN NAMES, IDENTIFYING NUMBERS, SERVICES, RANKS, AND RADIATION DOSES OF ALL PERSONNEL INVOLVED. AFTER COMPLETION, THE SUMMARIES WILL BE MADE AVAILABLE TO SCIENTIFIC ORGANIZATIONS FOR COMPLETION OF EPIDEMIOLOGICAL EVALUATIONS TO DETERMINE IF THERE IS ANY RELATIONSHIP BETWEEN LOW DOSES OF IONIZING RADIATION AND CERTAIN DISEASES.

SUPPORTED BY U.S. Dept. of Defense, Defense Nuclear Agency, Armed Forces Radiobiology Research Inst. funds n.a.

2.0143,

DISTRIBUTION OF PARASITIC DISEASES OF MILITARY IMPORTANCE IN THE PHILIPPINES

W.P. Carney, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, Medical Ecology Dept., *APO Box 14, San Francisco, California* 96263 (DN877409)

THE OBJECTIVE OF THIS STUDY WILL BE TO OBTAIN DATA ON THE DISTRIBUTION AND PREVALENCE OF PARASITIC DISEASES OF MILITARY IMPORTANCE THROUGHOUT THE PHILIPPINES THAT WILL AID IN THE IMPLEMENTATION OF EFFECTIVE PREVENTIVE PROGRAMS.

BIOMEDICAL SURVEYS WILL BE CONDUCTED THROUGHOUT PHILIPPINE ISLANDS FOCUSING ON THE DISTRIBUTION AND PREVALENCE OF MALARIA AND SCHISTOSOMIASIS. STOOL SPECIMENS, BLOOD SMEARS AND SERA WILL BE COLLECTED AND EXAMINED BY APPROPRIATE PARASITOLOGICAL AND IMMUNOLOGICAL DIAGNOSTIC TECHNIQUES. ALL SURVEY DATA WILL BE COMPUTERIZED SO THAT CURRENT STATUS REPORTS ON PARASITIC DISEASES OF MILITARY IMPORTANCE CAN BE PRODUCED UPON DEMAND. INITIAL EMPHASIS WILL FOCUS ON THE SURVEILLANCE OF DISEASES IN THE SOUTHERN AND CENTRAL PHILIPPINES SINCE LITTLE INFORMATION IS AVAILABLE FOR THESE REGIONS.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research & Development Command funds n.a.

2.0144,

METHODS AND PROCEDURES FOR IMPROVED REPORTING OF OUTPATIENT MEDICAL DATA

A.P. Jones, U.S. Dept. of Defense, Navy, Naval Health Research Center, Environmental & Social Medicine Div., *San Diego, California* 92152 (DN877531)

HEALTH CARE PLANNERS AND MANAGERS NEED ACCURATE DATA ON WORKLOADS, TYPES OF CASUALTIES AND DISEASES TO BE TREATED, UTILIZATION OF MEDICAL PERSONNEL AND BIOMEDICAL RISKS IN THE WORK ENVIRONMENT IN ORDER TO PROVIDE TIMELY PREVENTIVE AND TREATMENT SERVICES. PRESENT OUTPATIENT RECORD SYSTEMS GENERALLY ARE INADEQUATE FOR SUCH PURPOSES. THE PURPOSE OF THIS STUDY IS TO DEVISE AND DETERMINE THE FEASIBILITY OF IMPROVED REPORTING PROCEDURES FOR NAVY SHIPS AND SHORE DISPENSARIES AND TO PROVIDE A BASIS FOR ASSESSING THE SEVERITY AND RISK OF ENVIRONMENTAL HEALTH HAZARDS AS WELL AS OFFERING THE POTENTIAL FOR BETTER MANAGEMENT OF MEDICAL RESOURCES. THE FINAL OBJECTIVE OF THIS WORK UNIT WILL BE TO DEPICT PERSONNEL AND EQUIPMENT REQUIREMENTS. TO DEVISE NECESSARY DATA FORMS, AND TO DEVELOP PROPOSALS FOR REVISION OF EXISTING BUMED DIRECTIVES IN ORDER TO IMPLEMENT COST EFFECTIVE IMPROVEMENTS IN THE EXISTING OUTPATIENT MORBIDITY REPORTING SYSTEM.

A SICK CALL CARD WAS DEVELOPED TO RECORD INDIVIDUAL ILLNESSES AND INJURIES ABOARD DEPLOYED NAVY SHIPS FOR RESEARCH PURPOSES. THIS REPORTING PROCEDURE HAS BEEN EXPANDED AND REVISED AND IS NOW AVAILABLE IN A MACHINE-SCOREABLE FORM THAT PROVIDES ESSENTIAL DEMOGRAPHIC, OCCUPATIONAL, TREATMENT, AND DISPOSITION INFORMATION FOR PREVENTIVE MEDICINE AND EPIDEMIOLOGIC ANALYSES AND RESEARCH. THIS FORM WILL BE FURHTER MODIFIED FOR EXPERIMENTAL EVALUATION AT SHORE-BASED OUTPATIENT FACILITIES. MONTHLY OUTPATIENT MORBIDITY REPORTS AND OTHER MEDICAL REPORTS WILL BE GENERATED ON AN EXPERIMENTAL BASIS.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research & Development Command funds n.a.

2.0145,

DIAGNOSIS, EPIDEMIOLOGY AND TREATMENT OF HEPATITIS B VIRUS INFECTIONS IN SOUTHEAST ASIA

R.P. Beasley, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, Epidemiology & Clinical Investigation Dept., *APO Box 14, San Francisco, California* 96263 (DN041425)

THE MAJOR OBJECTIVES ARE TO: (1) DETERMINE THE MECHANISMS OF TRANSMISSION OF HEPATITIS B INFECTION; (2) IDENTIFY GROUPS SUITABLE FOR PROPHYLACTIC TRIALS; (3) UNDERSTAND THE FACTORS RELATING HBV INFECTIONS TO THE DEVELOPMENT OF CHRONIC LIVER DISEASE.

THE APPROACH OF THESE STUDIES IS EPIDEMIOLOGIC. THE PREVALENCE OF HEPATITIS B SURFACE ANTIGEN (HBSAG) AND HEPATITIS B SURFACE ANTIBODY (ANTI HBS) ARE STUDIED IN VARIOUS POPULATIONS TO DETERMINE WHAT DEMOGRAPHIC AND GEOGRAPHIC FACTORS ARE ASSOCIATED WITH INFECTION. CONVERSIONS OF ANTIGEN AND ANTIBODY STATUS ARE STUDIED IN VARIOUS POPULATIONS TO DETERMINE THE INCIDENCE OF NEW INFECTIONS AND IDENTIFY THE GROUPS AT HIGHEST RISK.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research & Development Command funds n.a.

2.0146,

HEALTH AND LONGEVITY IN RELATION TO LENGTH OF OCCUPATIONAL EXPOSURE TO THE NAVAL SUBMARINE ENVIRONMENT

W.L. Hunter, U.S. Dept. of Defense, Navy, Naval Submarine Medical Research Lab., Operational Medicine Dept., *Naval Submarine Base, Groton, Connecticut* 06340 (DN777382)

THE AIM OF THIS STUDY IS TO DETERMINE THE HEALTH EFFECTS OF PROLONGED OCCUPATIONAL EXPOSURE TO THE NUCLEAR POWERED SUBMARINE ENVIRONMENT. PARTICULAR ATTENTION WILL BE DIRECTED TOWARD OBTAINING INFORMATION REGARDING MORBIDITY/MORTALITY RELATED TO LOW-LEVEL RADIATION EXPOSURE RECEIVED IN THAT ENVIRONMENT. NEGATIVE FINDINGS WILL DOCUMENT THE SAFETY OF THE NUCLEAR-POWERED SUBMARINE FOR HUMAN HABITATION. POSITIVE FINDINGS ARE EXPECTED TO LEAD TO RECOMMENDATIONS SUCH AS: (A) FURTHER STUDIES TO DETERMINE ETIOLOGY OF DELETERIOUS HEALTH EFFECTS, (B) ASSESSMENT OF EXISTING ENVIRONMENTAL ENGINEERING SYSTEMS ABOARD SUBMARINES, AND (C) ALTERATIONS TO CURRENT PHYSICAL EXAMINATION REQUIREMENTS FOR CURRENT AND PAST SUBMARINE CREW MEMBERS.

THIS RECORD-LINKAGE PROJECT WILL COMPARE DISEASE PREVALENCE AND DISEASE-SPECIFIC MORTALITY RATES TO LENGTH OF SUBMARINE EXPERIENCE AND TO RADIATION EXPOSURE. THE PRINCIPAL DATA BASE WILL BE INFORMATION IN AUTOMATED DATA PROCESSING FILES MAINTAINED IN THE NAVY AND OTHER FEDERAL AGENCIES. IN ORDER TO DEVELOP A LARGE RISK BASE AMONG OLDER PERSONNEL, ATTENTION IS DIRECT TO RETIRED AND FLEET RESERVE PERSONNEL. THIS WORK UNIT WILL BE SUPPORTED BY A CONTRACT WITH YALE UNIVERSITY.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research & Development Command, National Naval Medical Center funds n.a.

2.0147,

THE EPIDEMIOLOGY AND POST-TREATMENT OUTCOMES OF TRAUMA IN NAVAL ENVIRONMENTS

R.F. Booth, U.S. Dept. of Defense, Navy, Naval Health Research Center, Environmental & Social Medicine Div., *San Diego, California* 92152 (DN977544)

ACCIDENTAL INJURIES ARE THE LEADING CAUSE OF HOSPITALIZATION AMONG NAVY ACTIVE DUTY PERSONNEL. THESE INJURIES MAKE A SUBSTANTIAL CONTRIBUTION TO MANDAYS LOST FROM THE JOB, DEMANDS FOE HEALTH CARE SERVICES, AND LONG-TERM DISABILITY AND MORTALITY FOR ACCIDENT VICTIMS. THE INTERACTION OF INDIVIDUAL, OCCUPATIONAL, AND ENVIRONMENTAL CHARACTERISTICS AS THEY RELATE TO THE INCIDENCE OF ACCIDENTAL INJURIES WILL BE INVESTIGATED. THE IMPLICATIONS OF AN INJURY-PRODUCING ACCIDENT FOR LENGTH OF HOSPITALIZATION, PROLONGED DISABILITY, PERFORMANCE EFFECTIVENESS, AND CAREER RETENTION OF ACCIDENT VICTIMS ALSO WILL BE INVESTIGATED. BY IDENTIFYNG THOSE POPULATIONS AND WORK SETTINGS WHERE THE RISKS OF TRAUMA ARE GREATEST, IT SHOULD BE POSSIBLE TO RECOMMEND MEANS FOR REDUCING THE NUMBER AND SEVERITY OF ACCIDENT CASUALTIES.

ANALYSES WILL BE CONDUCTED OF MEDICAL AND SERVICE HISTORY DATA FOR ALL NAVY ENLISTEES WHO WERE HOSPITALIZED FOR THE TREATMENT OF ACCIDENTAL INJURIES DURING 1965 THROUGH 1976. THE INCIDENCE OF TRAUMA-PRODUCING ACCIDENTS WILL BE RELATED TO THE VICTIM'S DEMOGRAPHIC AND MILITARY STATUS CHARACTERISTICS, OCCUPATION, JOB EXPERIENCE, AND WORK SETTING. DETAILED ANALYSES OF ORGANIZATIONAL AND ENVIRONMENTAL CIRCUMSTANCES SURROUNDING ACCIDENTAL INJURIES WILL BE POSSIBLE IF NAVAL SAFETY CENTER (NSC) RECORDS ARE USED IN CONJUNCTION WITH INPATIENT REORDS. A FOLLOW-UP STUDY WILL BE MADE OF INJURY VICTIMS TO DETERMINE HOW THE TYPE AND SEVERITY OF TRAUMA IS RELATED TO LENGTH OF HOSPITALIZATON, LONG-TERM

DISABILITY, SUBSEQUENT PERFORMANCE EFFECTIVENESS, AND CAREER RETENTION.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research & Development Command, National Naval Medical Center funds n.a.

2.0148,

THE PHYSIOLOGICAL, BIOCHEMICAL, AND PSYCHOLOGICAL EFFECTS OF 18-HOUR WORK-REST CYCLES DURING A 2-MONTH SUBMARINE PATROL

W.L. Hunter, U.S. Dept. of Defense, Navy, Naval Submarine Medical Research Lab., *Groton, Connecticut* 06340 (DN977564)

MOST TYPES OF PHYSIOLOGICAL AND PSYCHOLOGICAL STRESS ARE REGULARLY ACCOMPANIED BY INCREASED ADRENERGIC NERVOUS SYSTEM (ANS) ACTIVITY. THIS INCREASED ANS ACTIVITY IS REFLECTED QUITE ACCURATED BY AN INCREASED URINARY EXCRETION OF THE CATECHOLAMINES (CA), NOREPINEPHRINE AND EPINEPHRINE. IT IS POSSIBLE THAT CHRONIC ADJUSTMENT AND READJUSTMENT TO 18-HOUR DUTY CYCLES ABOARD SUBMARINES MAY PRODUCE CHANGES IN ANS ACTIVITY AND THUS, CA EXCRETION. CHANGES IN CA LEVELS COULD HAVE A VARIETY OF EFFECTS, SINCE THEY PLAY A ROLE IN CARDIOVASCULAR HOMEOSTATIS AND BEHAVIORAL FUNCTIONING. THE RECENT DEVELOPMENT OF A HIGHLY SENSITIVE TECHNIQUE MAKES IT POSSIBLE FOR THIS PILOT INVESTIGATION TO STUDY THE EFFECT OF WORK-REST CYCLE CHANGES DURING SUBMARINE PATROLS ON ANS ACTIVITY AS REFLECTED BY CA EXCRETION.

URINARY CA WILL BE MEASURED TO ASSESS THE EFFECT OF LONG-TERM CHANGES IN THE WORK-REST CYCLE DURING A RECENT OPERATIONAL SSBN PATROL. URINE SAMPLES WERE OBTAINED FROM 10 VOLUNTEER SUBMARINES EVERY 3 HOURS (INCLUDING THEIR SLEEP PERIOD) FOR 7 DAYS DURING AN EARLY, MID AND LATE PERIOD OF AN 8-WEEK SSBN PATROL. CONTROL (24 HR WORK-REST CYCLE) URINES WERE OBTAINED FROM THE MEN ONE MONTH AFTER THE PATROL. CYCLIC VARIATIONS IN THE CA MEASURES WILL BE RELATED TO ORAL TEMPERATURES, MOOD STATE, AND MEASURES OF SLEEP QUALITY THAT WERE TAKEN CONCOMITANTLY. ADJUSTMENT TO AN 18-HOUR WORK-REST CYCLE WILL ALSO BE CORRELATED WITH SUBMARINE QUALIFICATION, OFF-DUTY TRAINING PERFORMANCE, AND SICK CALL VISITS.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research & Development Command, National Naval Medical Center funds n.a.

2.0149,

PARASITIC DISEASES OF THREAT TO MILITARY OPERATIONS IN THE MIDDLE EAST AND NEARBY AFRICAN STATES

N.S. Mansour, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #3, Immunology & Parasitology Dept., *FPO, New York, New York* 09527 (DN977622)

TO MAP THE DISTRIBUTION OF HUMAN PARASITES IN THE MIDDLE TEAST AND SOME AFRICAN STATES IN ORDER TO IDENTIFY THE AREAS OF RISK TO THE MILITARY, TO FURNISH RELEVANT EPIDEMIOLOGICAL INFORMATION FOR FUTURE PLANNING OF DISEASE PREVENTION AND CONTROL, AND TO DEVELOP AND STANDARDIZE TECHNIQUES FOR FAST RELIABLE MEANS OF DIAGNOSIS AND DETECTION OF OBSCURE CONDITIONS.

PARASITOLOGICAL SURVEYS WILL BE CONDUCTED IN DIFFERENT AREAS OF NEARBY COUNTRIES. STOOL, URINE AND BLOOD SMEARS WILL BE COLLECTED AND EXAMINED UTILIZING STANDARD PARSITOLOGICAL METHODS. SERA WILL BE TESTED BY ESTABLISHED SEROLOGICAL TECHNIQUES TO DETERMINE PRESENT AND PAST EXPERIENCE WITH THE DIFERENT PARASITES OF IMPORTANCE. WHERE APPROPRIATE, INTERMEDIATE HOSTS, VECTORS AND RESERVOIRS HOSTS WILL BE COLLECTED IDENTIFIED AND EXAMINED. MAPS WILL BE PREPARED TO DEPICT THE DISTRIBUTION OF THE IMPORTANT PARASITES AND THEIR RELEVANT EPIDEMIOLOGIC DATA.

LONGITUDINAL HEALTH PATTERNS AMONG CAREER NAVAL PERSONNEL

A. Hoiberg, U.S. Dept. of Defense, Navy, Naval Health Research Center, Environmental & Social Medicine Div., *San Diego, California* 92152 (DN477092)

MORBIDITY STUDIES USED IN MEDICAL PLANNING PROVIDE RATES OF SPECIFIC ILLNESSES AND INJURIES FOR POPULATIONS AT RISK WITHIN A PARTICULAR TIME FRAME, TYPICALLY A YEAR. LESS COMMON ARE INCIDENCE STUDIES OF ILLNESS PATTERNS OVER AN EXTENDED PERIOD OF TIME AS IN AN OCCUPATIONAL CAREER. SINCE PREVIOUS RESEARCH OF LIFE STRESSES AND HEALTH CHANGE SUGGESTS THAT ILLNESSES TEND TO CLUSTER PERIODICALY IN AN INDIVIDUAL'S LIFE, THE OBJECTIVE OF THIS WORK UNIT IS TO DETERMINE MORE PRECISELY THE MANNER IN WHICH SUCH OCCURS AMONG PERSONNEL OVER THE COURSE OF A NAVAL CAREER. SUCH INFORMATION COULD BE OF VALUE IN FORMULATING BETTER PROGNOSTIC GUIDELINES OF DIFFERENT HEALTH PROBLEMS AS WELL AS IN DEVELOPING IMPROVED MEDICAL SCREENING AND OCCUPATINAL HEALTH PROGRAMS AT A TIME DURING WHICH GREATER RELIANCE MUST BE PLACED ON EFFECTIVE CAREER PERSONNEL IN THE NAVY AND MARINE CORPS.

DATA ON ALL HOSPITALIZATIONS, BOARD ACTIONS, AND DEATHS AMONG NAVAL PERSONNEL WILL BE RETROSPECTIVELY ANALYZED FOR A 9-YEAR PERIOD. WITH DEMOGRAPHIC AND SERVICE HISTORY INFORMATION ALSO ON COMPUTER TAPES AT THIS CENTER, INCIDENCE OF SINGLE AND MULTIPLE EPISODES OF ILLNESS OR INJURY WILL BE DETERMINED IN RELATION TO AGE, OCCUPATION, DUTY ASSIGNMENTS, AND SERVICE STATUS CHANGES. SPECIFIC HYPOTHESES WILL BE TESTED THROUGH PROSPECTIVE LONGITUDINAL STUDIES OF COHORT SAMPLES AS IS CURRENTLY IN PROGRESS FOR CARDIOVASCULAR DISEASE, GASTROINTESTINAL, AND PSYCHIATRIC DISORDERS.

ARTHROPOD-VECTOR-DISEASE INTERRELATIONSHIPS

H. Hoogstraal, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #3, Medical Zoology Dept., *FPO, New York, New York* 09527 (DN477104)

TO INVESTIGATE AND INCREASE KNOWLEDGE OF BLOODSUCKING ARTHROPODS (TICKS, MITES, FLEAS, MOSQUITOES, ETC) KNOWN OR STRONGLY SUSPECTED TO HARBOR AND TRANSMIT VIRAL AND RICKETTSIAL PATHOGENS AND PROTOZOAL AND HELMINTH PARASITES HAZARDOUS TO MILITARY PERSONNEL. IDENTIFY HOSTS AND DEFINE LIFE CYCLES, BIOLOGY, GEOGRAPHIC DISTRIBUTION, AND OTHER EPIDEMIOLOGICALLY IMPORTANT FACTORS.

VERTEBRATES AND BLOODSUCKING ARTHROPODS ARE SYSTEMATICALLY COLLECTED FOR PATHOGEN ISOLATION AND DISEASE TRANSMISSION STUDIES AND FOR EVALUATION OF ECOLOGICAL AND EPIDEMIOLOGICAL FACTORS INFLUENCING DISEASE TRANSMISSION.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research & Development Command, National Naval Medical Center funds n.a.

2.0152,

INFECTIOUS DISEASE RISKS TO TRANSLOCATED PERSONS IN INDONESIA

D.T. Dennis, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, *Jakarta Det., APO, San Francisco, California* 96356 (DN141419)

TO IDENTIFY IN INFECTIOUS DISEASES IN OUTER ISLANDS OF INDONESIA OF RISK TO IMMIGRANTS WITH PRIOR DISEASE EXPOSURE UNLIKE THAT OF THE NEW ENVIRONMENT. THE STUDY HAS 3 PHASES: (1) BASELINE ASSESSMENT DISEASE AND DISEASE EXPOSURE OF INDIGENOUS AND PREVIOUSLY TRANSLOCATED PERSONS LIVING IN AREAS SELECTED FOR FUTURE TRANSSETTLEMENT (STRESSING INFECTIOUS DISEASES, THEIR ENVIRONMENTAL SOURCES, RESERVOIRS AND VECTORS); (2) ASSESSMENT OF DISEASE EXPERIENCE AMONG TRANSMIGRANT POPULATIONS PRIOR TO THEIR ARRIVAL IN TRANSETTLEMENT AREAS; (3) RE-ASSESSMENT OF DISEASE IN TRANSLOCATED PERSONS AT INTERVALS FOLLOWING IMMIGRATION.

FIELD TEAMS COLLECT HUMAN BLOOD, STOOL, AND SERA SPECIMENS, RODENTS AND THEIR ECTOPARASITES, MOSQUITOES, AND SUSPECTED INTERMEDIATE HOSTS OF DISEASE AT SITES SELECTED FOR FUTURE TRANSSETTLEMENT. PHYSICAL EXAMINATIONS OF STUDY POPULATIONS BY TEAM PHYSICIANS ARE PERFORMED, AND INFORMATION RELEVANT TO THE ECOLOGY AND EPIDEMIOLOGY OF INFECTIOUS AND ENVIRONMENTAL DISEASES IS GATHERED.

2.0153,

ANTIBIOTIC RESISTANT NEISSERIA GONORRHOEAE: DETERMINATION OF PREVALENCE AND SPREAD IN INDONESIA

A.B. Cobet, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, *Jakarta Det., APO, San Francisco, California* 96356 (DN877410)

TO DETERMINE THE PREVALENCE OF NEISSERIA GONORRHOEAE (N. GC.),ESPECIALLY PENICILLIN RESISTANT STRAINS IN SELECTED MAJOR SEA PORTS OF INDONESIA; DETERMINE THE MINIMUM INHIBITORY CONCENTRATION OF SELECTED ANTIBIOTICS TO N. GC; AND DETERMINE THE AMINO ACID NUTRITIONAL PROFILES OF THESE ORGANISMS FOR USE AS MARKERS IN THE EPIDEMIOLOGIC STUDIES.

SPECIMENS OBTAINED FROM PROMISCUOUS, SEXUALLY ACTIVE POPULATIONS WILL BE CULTURES FOR NEISSERIA SP. AND CHARACTERIZED BIOCHEMICALLY FOR N. GC. AND BETA-LACTAMASE (PENICILLINASE) PRODUCTION. THE MINIMAL INHIBITORY CONCENTRATION (MIC) OF MAJOR USEFUL ANTIBIOTICS WILL BE ASSAYED BY THE AGAR DILUTION METHOD AND AMINO ACID NUTRITIONAL PROFILES WILL BE DONE BY THE METHOD OF CATLIN. ACQUISITION OF SPECIMENS WILL BE ACCOMPLISHED IN CONJUCTION WITH THE INDONESIAN MINISTRY OF HEALTH,M VENEREAL DISEASE CONTROL PROGRAM.

IMMUNITY TO FILARIAL WORMS: THE RESPONSE OF HUMANS TO INFECTION.

J. Palmieri, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, *Jakarta Det., APO, San Francisco, California* 96356 (DN877412)

IMMUNOLOGY : TO DETERMINE IF (1) TREATMENT OF HUMANS WITH DIETHYLCARBAMAZINE (DEC)FOR BRUGIAN FILARIASIS AFFECT THEIR IMMUNITY TO MICROFILARIAE (MF) AND (2) IF ANTIBODIES TO THE MF STAGES OF WUCHERERIA AND BRUGIA CROSS REACT IN VITRO USING THE ANTIBODY MEDIATED-LEUCOCYTE TOXICITY REACTION., EPIDEMIOLOGY: TO DETERMINE IF MASS CHEMOTHERAPY WITH DEC BREAKS MOSQUITO BORNE TRANSMISSION OF SUBPERIODIC BRUGIA MALAYI AND TO DEFINE THE ROLE OF ANIMALS AS RESERVOIRS OF INFECT FOR MAN.

BASELINE DATA ON THE PREVALENCE AND DENSITY OF CIRCULATION MF, EXPOSURE RATES TO INFECTIVE MOSQUITOES AND THE PREVALENCE OF ANTI-FILARIAL ANTIBODIES IN PEOPLE LIVING IN 2 VILLAGES IN S. KALIMANTAN HAVE BEEN MONITORED FOR 18 MONTHS. THESE PARAMETERS WILL BE MEASURED AGAIN AFTER MASS THERAPY WITH DEC TO DETERMINE THE IMPACT OF THIS TREATMENT OF FILARIAL TRANSMISSION. THE PREVALENCE OF B MALAYI IN ANIMALS WILL BE DETERMINED TO EVALUATE THE IMPORTANCE OF THIS PUTATIVE RESERVOIR OF INFECTION TO MAN.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research & Development Command, National Naval Medical Center funds n.a.

2.0155,

IMMUNE MECHANISMS ASSOCIATED WITH SCRUB TYPHUS RICKETTSIAE.

D.R. Woodman, U.S. Dept. of Defense, Navy, Naval Medical Research Inst., Div. of Rickettsial Diseases, *Bethesda, Maryland* 20014 (DN877457)

THE POTENTIAL AND HISTORICAL THREATS OF SCRUB TYPHUS TO MILITARY OPERATIONS ARE WELL RECOGNIZED. ALTHOUGH NO EFFECTIVE VACCINE IS CURRENTLY AVAILABLE, OUR DEPARTMENT IS ENGAGED IN AN INTENSIVE RESEARCH PROGRAM TOWARDS SUCH A GOAL. THE OBJECTIVE IS TO FULLY INVESTIGATE THE IMMUNE MECHANISMS ASSOCIATED WITH EXPERIMENTAL SCRUB TYPHUS INFECTIONS, SO THAT CANDIDATE VACCINES CAN BE ADEQUATELY EVALUATED IN THE LABORATORY. IN PARTICULAR, THE ROLES OF HUMORAL (ANTIBODY) AND CELL-MEDIATED IMMUNITY (CMI) WILL BE QUANTIFIED. THIS MUST BE ACCOMPLISHED IN ORDER TO MONITOR THE RESPONSES OF CANDIDATE VACCINES.

METHODS TO QUANTIFY BOTH HUMORAL AND CMI RESPONSES TO THE AGENTS OF SCRUB TYPHUS WILL BE SIMULTANEOUSLY DEVELOPED IN BOTH LABORATORY ANIMAL AND IN VITRO EXPERIMENTS. ONCE DEVELOPED THESE METHODS WILL BE USED TO IDENTIFY IMMUNE MECHANISMS ASSOCIATED WITH RECOVERY FROM AND RESISTANCE TO RICKETTSIA TSUTSUGAMUSHI INFECTION. RESULTS OF THESE EXPERIMENTS WILL PROVIDE IMMUNOLOGICAL CRITERIA FOR THE EVALUATION OF SPECIFIC VACCINE ANTIGENS AND EXPERIMENTAL IMMUNIZATION PROCEDURES. INTACT INFECTIOUS ORGANISMS AND PURIFIED CELL WALL FRACTIONS WILL BE CONSIDERED AS POTENTIAL ANTIGENS FOR VACCINE DEVELOPMENT. A CMI-BASED SKIN TEST TO FACILITATE RAPID DIAGNOSIS AND EPIDEMIOLOGICAL STUDIES OF SCRUB TYPHUS WILL BE AN IMPORTANT TOOL FOR THIS WORK.

2.0156,

ARBOVIRAL DISEASES IN INDONESIA; EPIDEMIOLOGY AND DISTRIBUTION

J.G. Olson, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, *Jakarta Det., APO, San Francisco, California* 96356 (DN877464)

TO IDENTIFY ARTHROPOD-BORNE VIRUSES IN INDONESIA WHICH ARE CAUSING INFECTION IN HUMANS AND ANIMALS AND TO DETERMINE THE RELATIVE IMPORTANCE AND DISTRIBUTION OF EACH AS A CAUSE OF ILLNESS IN MAN.

VIRUS ISOLATIONS WILL BE ATTEMPTED FROM HUMAN CLINICAL SPECIMENS, ANIMAL SERA AND POOLED ARTHROPODS COLLECTED IN INDONESIA. SEROLOGIC EVIDENCE OF ARBOVIRAL INFECTION WILL BE SOUGHT FROM BOTH HUMAN AND ANIMAL SERA USING HAEMAGGLUTINATION INHIBITION AND NEUTRALIZATION TESTS FOR ANTIBODIES AGAINST VIRUSES KNOWN TO BE ACTIVE IN SOUTHEAST ASIA AND THE WESTERN PACIFIC.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research & Development Command, National Naval Medical Center funds n.a.

2.0157,

EXPLORATION OF THE RELATIONS BETWEEN EYE COLOR, SELECTED PHYSIOLOGICAL MEASURES AND INDIVIDUAL NOISE SUSCEPTIBILITY

N.G. Hoger, U.S. Dept. of Defense, Navy, Naval Aerospace Medical Research Lab., *Pensacola, Florida* 32512 (DN877532)

To explore the relations between eye color, selected physiological measures and individual noise susceptibility. Identification of any such relationships would have implications toward the prevention of noise-induced hearing loss among naval personnel working in potentially hazardous noise environments.

Examine the extensive audiometric data obtained from subjects in the thousand aviator study and subjects in the control group of the repatriated prisoner of war (RPW) study. From the records of those subjects exhibiting hearing levels of 50 db or greater at 3000, 4000 or 6000 Hz (subject group I) and those subjects exhibiting hearing levels of 25 db or less at 500 through 6000 Hz (subject group II), determine eye color, percent body fat, systolic and diastolic blood pressures (sitting and supine), serum uric acid, cholesterol, and triglycerides. Conduct appropriate statistical analyses to determine possible relations between individual noise susceptibility, eye color and the various physiological measures. If findings warrant, develop a research plan to conduct selected tests on those subjects returning to Pensacola for medical follow-up as part of the thousand aviator and RPW/control group studies.

2.0158,

AMEBIASIS IN ASIA: DIAGNOSIS, EPIDEMIOLOGY AND IMMUNOLOGY OF ENTAMOEBA HISTOLYTICA

J.H. Cross, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, Medical Ecology Dept., *APO Box 14, San Francisco, California* 96263 (DN941411)

AMEBIASIS, INTESTINAL OR EXTRAINTESTINAL, CAN BE A DIAGNOSTIC PROBLEM IN MILITARY AS WELL AS CIVILIAN MEDICAL PRACTICE. THE OBJECTIVE OF THIS STUDY IS TO IMPROVE UPON THE CLASSICAL METHODS OF DETECTING INFECTIONS OF ENTAMOEBA HISTOLYTICA; TO OBTAIN INFORMATION ON THE PREVALENCE AND DISTRIBUTION OF THE PARASITE AND THE DISEASE BY STOOL AND SEROLOGIC EXAMINATIONS; AND TO STUDY THE ANTIGENICITY OF STRAINS OF THE PARASITE IN ORDER TO REFINE IMMUNOLOGIC METHODS OF DIAGNOSIS.

CONVENTIONAL AS WELL AS NEWER METHODS OF STOOL EXAMINATIONS WILL BE USED TO DETECT E. HISTOLYTICA IN SPECIMENS FROM SYMPTOMATIC AND ASYMPTOMATIC INDIVIDUALS. STRAINS OF THE PARASITE WILL BE ISOLATED IN CULTURE AND THE ANTIGENICITY OF EACH ANALYSED BY IMMUNOELECTROPHORESIS (IEP) AND 2-DIMENSIONAL ELECTROPHORESIS (2D-IEP). HIGHLY ANTIGENIC COMPONENTS WILL BE USED FOR DEVELOPING MORE SENSITIVE SEROLOGIC TESTS FOR DIAGNOSIS AND SEROEPIDEMIOLOGICAL STUDIES. NEWER METHODS, SEROLOGIC AND STOOL, WILL BE USED IN THE DIAGNOSIS OF INTESTINAL AND EXTRAINTESTINAL AMEBIASIS IN THE PHILIPPINES.

A MORBIDITY FORECAST MODEL FOR OPERATIONAL DEPLOYMENTS

A.P. Jones, U.S. Dept. of Defense, Navy, Naval Health Research Center, Environmental & Social Medicine Div., *San Diego, California* 92152 (DN777276)

THE OPERATIONAL READINESS AND EFFECTIVENESS OF COMBAT SHIPS DEPEND UPON THE PHYSICAL AND MENTAL FITNESS OF THE CREW. IN ORDER TO PLAN ADEQUATE MEDICAL SUPPORT FOR FLEET OPERATIONS, IT IS IMPORTANT TO IDENTIFY PERSONNEL AND SITUATIONAL FACTORS THAT INCREASE THE RISK OF MORBIDITY OR IMPAIRED EFFECTIVENESS AND TO DEVELOP A MODEL FOR PREDICTING FLEET UNITS AND CREW ELEMENTS AT GRESTEST RISK FOR ILLNESS AND INJURY DURING DEPLOYMENT PERIODS. THE ASSOCIATED COST IN MAN-DAYS LOST AND PERSONNEL TURNOVER, AND THE ADEQUACY OF PREVENTION AND HEALTH CARE ABOARD SHIP.

DATA FROM A PREVIOUS STUDY OF 20 COMBAT SHIPS WERE UED TO ESTABLISH THE PARAMETERS OF A MORBIDITY FORECAST MODEL TO PREDICT CASUALTIES DURING OPERATIONAL DEPLOYMENTS. THE FOLLOWING PARAMETERS ARE INCLUDED: (1) AGE, PHYSICAL CHARACTERISTICS, AND CLASS OF SHIP; (2) MISSION AND TECHNOLOGY (WEAPONS SYSTEMS); (3) PERSONNEL CHARACTERISTICS; (4) OPERATIONAL SCHEDULE (GIOGRAPHY AND SEASON, DEPLOYMENT PHASES AND DURATION, SPECIFIC PORTS VISITED), (5) HABITABILITY CHARACTERISTICS OF WORK ENVIRONMENT, AND (6) ORGANIZATIONAL FACTORS (CLIMATE AND MANPOWER UTILIZATION). THE SECOND PHASE OF THE STUDY MEASURED ENVIRONMENTAL CONDITIONS, PERSONNEL VARIABLES, ORGANIZATIONAL FACTORS, AND OPERATIONAL ACTIVITIES FOR A SAMPLE OF 7 AMPHIBIOUS ASSAULT SHIPS AT THE START OF DEPLOYMENTS TO THE WESTERN PACIFIC U SING MODIFIED TEST INSTRUMENTS AND PROCEDURES DEVELOPED PREVIOUSLY.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research & Development Command, National Naval Medical Center funds n.a.

FILARIASIS IN INDONESIA. CLINICAL AND EPIDEMIOLOGIC FEATURES RELATED TO RISK, PREVENTION AND TREATMENT OF DISEASE

D.T. Dennis, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, *Jakarta Det., APO, San Francisco, California* 96356 (DN777320)

TO DEFINE CLINICAL AND EPIDEMIOLOGIC FEATURES OF FILARIASIS IN SELECTED REPRESENTATIVE SITES IN INDONESIA; TO DETERMINE THE GEOGRAPHIC DISTRIBUTION OF FILARIASIS IN INDONESIA; TO IDENTIFY VECTORS, THEIR BEHAVIOR AND ECOLOGIC REQUIREMENTS AND, TO FORMULATE GUIDELINES OF PREVENTION, CONTROL AND MANAGEMENT OF DISEASE. TO DOCUMENT PARASITOLOGIC AND CLINICAL RESPONSES TO STANDARD TREATMENT WITH DIETHYLCARBAMAZINE IN PERSONS INFECTED WITH THE VARIOUS SPECIES OF INDONESIAN FILARIA, INCLUDING THE TIMOR FILARIA.

INTENSIVE STUDIES WILL BE CONTINUED OF FILARIASIS IN SMALL, CAREFULLY DEFINED POPULATIONS AT UNDISTURBED FOCI OF TRANSMISSION. THIS INCLUDES DEMOGRAPHIC, PARASITOLOGIC, CLINICAL, HUMAN BEHAVIOR AND VECTOR DATA COLLECTIONS. DOCUMENTATION OF PARASITOLOGIC AND CLINICAL RESPONSES TO STANDARD TREATMENT WITH DIETHYLCARBAMAZINE WILL BE CONTINUED BY MONITORING INDONESIAN MINISTRY OF HEALTH TREATMENT PROGRAMS.

2.0162,

ANIMAL INFLUENZA VIRUSES AND THEIR POSSIBLE ROLE IN HUMAN INFLUENZA EPIDEMIOLOGY

T.G. Ksiazek, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, Virology Dept., *APO, San Francisco, California* 96263 (DN977620)

TO INVESTIGATE TYPE A INFLUENZA VIRUSES IN FERAL AND DOMESTIC ANIMALS IN ORDER TO ASSESS THE ROLE OF THESE VIRUSES IN THE ORIGIN OF NEW OR RECURRENT INFLUENZA SUBTYPES. THE STUDIES WILL BE CARRIED ON IN THE WESTERN PACIFIC INCLUDING THE INDONESIAN AND PHILIPPINE ARCHIPELAGOES, AN AREA OF THE WORLD RICH IN FAUNA AND FROM WHICH RECENT NEW SUBTYPES OF HUMAN INFLUENZA HAVE EMERGED.

SPECIMENS FROM ANIMALS WILL BE TAKEN IN CONJUNCTION WITH STUDIES INVESTIGATING THE ECOLOGY OF ARBOVIRUSES IN INDONESIA

AND THE PHILIPPINES. SWABS OF THE CLOACA AND THE RESPIRATORY TRACT IN BIRDS AND OF THE RESPIRATORY TRACT OF MAMMALS WILL BE TAKEN AND ISOLATION OF VIRUSES ATTEMPTED FROM THEM. ISOLATIONS WILL BE ATTEMPTED IN EMBRYONATED CHICKEN EMBRYOS OR EGG-BIT CULTURES AS WILL AS A CANINE KIDNEY-CELL-LINE. HEMAGEL DIFFUSION, AND NEURAMINIDASE INHIBITION TESTS. RECORDS OF LOCATION, SPECIES, DATA, SEX, AGE, AND SOURCE WILL BE KEPT AND ANALYZED THROUGH THE NAMRU-2 BIOSTATISTICS DEPARTMENT. SUMMARY STATISTICS AND DETAILED LISTS OF ANIMALS SAMPLED AND RESULTS WILL BE SENT TO THE WHO COLLABORATING CENTER FOR THE ECOLOGY OF INFLUENZA VIRUSES IN ANIMALS FOR INCLUSION IN THE SHO DATA BASE ON THIS SUBJECT.

SEAFARERS AS AN INDEX OF PARASITIC DISEASES OF THE INDONESIAN ARCHIPELAGO

J. Palmieri, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, *APO Box 14, Taiwan, San Francisco, California* 96263 (DN977629)

TO DETERMINE WHETHER INTER-ISLAND SEAFARERS LIVING ALONG THE NORTH COAST OF WEST JAVA MIGHT SERVE AS AN INDICATOR GROUP OF PARASITIC IDSEASES OF A LARGER GEOGRAPHIC AREA.

SMALL COMMUNITIES OF NATIVE SEAFARERS AND THEIR FAMILIES LIVING ALONG WITH NORTH COAST OF JAVA WILL BE SELECTED AS POTENTIAL INDEX POPULATIONS. THESE SEAFARERS USE SAIL-POWERED PRAUS TO TRADE ALONG THE COASTLINES OF THE MORE THAN 1,000 INHAABITED ISLANDS OF INDONESIA. APPROXIMATELY 100 SEAFARERS AND THEIR FAMILIES WILL BE EXAMINED FOR PROTOZOAN AND HELMINTH PARASITES BY STANDARD LABORATORY METHODS. PARASITIC DISEASE PATTERNS WILL BE RELATED TO SPECIFIC EPIDEMIOLOGIC MARKERS, ESPECIALLY ENVIRONMENTAL AND GEOGRAPHIC EXPOSURES, AND PREDICTION MODELS OF INFECTIOUS DISEASE RISK WILL BE DEVELOPED. PARTICULAR ATTENTION WILL BE PAID TO CHLOROQUINE RESISTANT STRAINS OF MALARIA, TREMATODE INFECTIONS AND FILARIASIS SINCE THESE HAVE FOCALLY DISTINCT GEOGRAPHIC DISTRIBUTION.

2.0164,

DETECTION OF HYDATID DISEASE IN RESIDENTS OF LINDU VALLEY, CENTRAL SULAWESI, INDONESIA

J.R. Palmieri, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, *APO Box 14, Taiwan, San Francisco, California* 96263 (DN977630)

TO DETERMINE THE PREVALENCE OF ECHINOCOCCOSIS IN HUMAN INHABITANTS OF LINDU VALLEY, CENTRAL SULAWESI, USING SEROLOGIC METHODS AND TO DETERMINE THE EPIDEMIOLOGY OF HYDATID DISEASE IN THE LINDU VALLEY BY EXAMINING DEFINITIVE AND INTERMEDIATE HOSTS.

APPROXIMATELY 400 INDONESIAN CIVILIANS LIVING ALONG THE SHORE OF LAKE LINDU WILL BE REGISTERED AND THEIR RELATIONSHIP WITH DOGS FOUND INFECTED WITH ECHINOCOCCUS GRANULOSUS DETERMINED. SERUM SPECIMENS WILL BE OBTAINED AND EXAMINED FOR ECHINOCOCCAL ANTIBODIES BY THE INDIRECT HEMNAGGLUTINATIONA DN BE SCREENED FOR ECHINOCOCCAL INFECTION. DOGS WILL BE PURGED AND STOOLS COLLECTED AND INDIVIDUALLY EXAMINED FOR E. GRANULOSUS. A SURVEY OF NATURALLY INFECTED INTERMEDIATE HOSTS WILL BE CONDUCTED.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2 funds n.a.

2.0165,

EVALUATION OF THE ELISA TEST FOR THE SERODIAGNOSIS OF ORIENTAL SCHISTOSOMIASIS

J.H. Cross, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #2, Medical Ecology Dept., *APO Box 14, San Francisco, California* 96263 (DN777371)

TO EVALUATE THE NEWLY DESCRIBED ENZYME-LINKED IMMUNOSORBENT ASSAY (ELISA) IN THE SERODIAGNOSIS OF SCHISTOSOMIASIS JAPONICA, TO APPLY THE TEST TO STUDIES ON THE SEROEPIDEMIOLOGY OF SCHISTOSOME INFECTIONS IN THE FAT EAST, AND TO DETERMINE THE SPECIFICITY AND SENSITIVITY OF ANTIGENS OF VARIOUS STAGES OF THE PARASITES.

LABORATORY ANIMALS WILL BE EXPOSED TO INFECTIONS WITH SCHISTOSOMA JAPONICUM OR IMMUNIZED WITH ANTIGENS FROM VARIOUS STAGES OF THE PARASITE. SERA WILL BE COLLECTED FROM THE ANIMALS AND TESTED AGAINST CERCARIAL, EGG, SCHISTOSOMULA AND ADULT WORM ANTIGENS. ONCE THE TECHNIQUES ARE ESTABLISHED AND FOUND TO BE SATISFACTORY, SERA FROM PATIENTS IN THE PHILIPPINES WILL BE COLLECTED AND TESTED AND CORRELATIONS MADE BETWEEN TEST RESULTS INFECTION AND DISEASE. THE TEST WILL BE ADAPTED TO MICROMETHODS AND SERA FROM PEOPLE IN ENDEMIC AREAS WILL BE COLLECTED AND SEROEPIDEMIOLOGICAL SURVEYS DONE TO DETERMINE THE PREVALENCE OF SCHISTOSOMIASIS.

STUDIES ON THE ASSOCIATION OF SCHISTOSOMIASIS AND MALIGNANCY, WITH PARTICULAR EMPHASIS ON SCHISTOSOMAL POLYPOSIS OF THE COLON

N.A. El Masry, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #3, Clinical Tropical Medicine Dept., *FPO, New York, New York* 09527 (DN777373)

Schistosomiasis poses an extraordinary threat to military personnel in endemic areas. Infection is easily acquired and results in both early morbidity and the possibility of very long-term service connected illness. The purpose of this study is to investigate the possible association of intestinal schistosomal polyposis and carcinoma of the colon.

OBJECTIVES: (1) To study the available statistics on cancer of the colon in Egypt and its association with Schistosoma mansoni (and polyposis). To take biopsy of polyps at various intervals; to study the incidence of malignancy in patients treated with repetitive courses of niridazole compared to those treated with tartar emetic and untreated patients. (3) Leukocyte typing for determining whether these polyp patients are genetically different from patients with S. Mansoni elsewhere. (4) To study the bladder cancer association to urinary schistosomaisis by blood and urine examination by various immunological testing procedures.

SUPPORTED BY U.S. Dept. of Defense, Navy, Naval Medical Research Unit #3 funds n.a.

2.0167,

DISEASES OF MILITARY RELEVANCE: THE INTERACTION OF HEPATITIS B AND SCHISTOSOMIASIS

S. Bassily, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #3, Clinical Tropical Medicine Dept., *FPO, New York, New York* 09527 (DN977581)

HEPATITIS B AND SCHISTOSOMIASIS PRESENT A CHALLENGE TO MILITARY OPERATIONS IN DEVELOPING COUNTRIES BECAUSE OF THEIR PREVALENCE AND THE ABSENCE OF PROPHYLACTIC VACCINES OR DRUGS. SINCE DUAL INFECTIONS WOULD BE EXPECTED TO OCCUR FREQUENTLY IN PERSONNEL DEPLOYED IN THESE AREAS, THE INTERACTION BETWEEN THE TWO DISEASES MUST BE DELINEATED. IT IS IMPERATIVE TO DETERMINE THE EFFECT OF SCHISTOSOMIASIS ON HEPATITIS B CARRIAGE RATES SINCE CARRIERS ARE AN IMPORTANT RESERVOIR OF DISEASE AND TO DETERMINE THE CLINICAL MORBIDITY ASSOCIATED WITH DUAL INFECTION. THIS STUDY ADDRESSES BOTH ISSUES: THE PREVALENCE OF HEPATITIS B CARRIERS WILL BE ESTABLISHED IN POPULATION SUBGROUPS WITH VARYING DEGREES OF SCHISTOSOMIASIS; AND THE 2 YEAR MORBIDITY OF DUAL INFECTION WILL BE COMPARED WITH THAT OF EITHER DISEAS E ALONE.

THE STUDY INVOLVES TWO RURAL EGYPTIAN VILLAGES WHOSE MALE INHABITANTS ARE REGULARLY SCREENED BY OTHER INVESTIGATORS AT 6 MONTH INTERVALS FOR HEPATITIS B SURFACE ANTIGEN AND ANTIBODY. LIMITED PHYSICAL EXAMINATION AND URINE AND STOOL EXAMINATIONS WILL BE PERFORMED ON ALL THESE MALE INDIVIDUALS TO ESTABLISH THE PRESENCE AND INTENSITY OF SCHISTOSOMIASIS IN THE VILLAGERS. THIS DATA WILL THEN BE COMPARED WITH THE PREVIOUSLY OBTAINED SEROLOGICAL DATA. FIFTY VILLAGERS WITH INTESTINAL SCHISTOSOMIASIS, 50 WITH HEPATITIS B ANTIGENEMIA AND 50 WITH BOTH CONDITIONS WHO CONSENT TO ANNUAL HOSPITALIZATION FOR IN DEPTH CLINICAL EVALUATION WILL BE FOLLOWED FOR 2 YEARS IN ORDER TO ASSESS THE RESPECTIVE CLINICAL MORBIDITY OF THE 3 DISEASE STATES.

MAGNITUDE OF THE BUBONIC PLAGUE THREAT IN THE ARAB REPUBLIC OF EGYPT

B.A. Botros, U.S. Dept. of Defense, Navy, Naval Medical Research Unit #3, Veterinary Medicine Dept., *FPO, New York, New York* 09527 (DN877493)

DOCUMENTED, SPORADIC OUTBRAKES OF PLAGUE STRUCK EGYPT AS LATE AS 1974, AND IN 1976, SOME CASES WERE SUSPECTED TO HAVE OCCURRED IN THE SUEZ AREA. THIS DISEASE IS PERPETUATED IN NATURE AS WILD OR SYLVATIC PLAGUE, I.E., ENDEMIC FOCI OF INFECTED ANIMALS. A STUDY IS REQUIRED TO EVALUATE THE PLAGUE HAZARD TO U.S. MILITARY PERSONNEL IN THE ARAB RUEPUBLIC OF EGYPT; THIS MAY BE ACCOMPLISHED BY: (1) DETERMINING THE GEOGRAPHIC AREA WHERE PLAGUE MIGHT BE A PROBLEM, (2) DETERMINING WHICH RODENT SPECIES ARE HARBORING THE DISEASE, (3) DETERMINING THE EXTENT OF SYLVATIC PLAGUED IN THE EGYPTIAN RODENT POPULATION.

WILD ANIMALS, BOTH FROM INHABITED AND NON-INHABITED AREAS, ARE BEING TRAPPED ALIVE IN LOCALITIES KNOWN OR SUSPECTED TO HAVE PLAGUE. BLOOD IS COLLECTED AND EXAMINED USING THE PASSIVE HEMAGGLUTINATION TECHNIQUE FOR YERSINIA PESTIS (PLAGUE ANTIBODIES). THE RESULTS OF THIS STUDY WILL IDENTIFY ENDEMIC FOCI AND WILL ESTIMATE THE PREVALENCE OF DISEASE IN THE NATIVE RODENT POPULATION.

MORBIDITY FORECAST MODEL FOR COLD WEATHER OPERATIONS

L.M. Dean, U.S. Dept. of Defense, Navy, Naval Submarine Medical Research Lab., Personnel Psychology Dept., *Naval Submarine Base, Groton, Connecticut* 06340 (DN977623)

THE OPERATIONAL EFFECTIVENESS OF NAVY AND MARINE CORPS PERSONNEL IN COLD ENVIRONMENTS DEPENDS UPON THE PHYSICAL AND MENTAL FITNESS OF THE TROOPS, THE OPERATIONAL OBJECTIVES, AND OTHER SITUATIONAL AND ENVIRONMENTAL FACTORS. IN ORDER TO PLAN COLD WEATHER OPERATIONS, IT IS IMPORTANT TO IDENTIFY THE PERSONEL AND SITUATIONAL FACTORS THAT INCREASE THE RISK OF MORBIDITY OR IMPAIRED EFFECTIVENESS AND TO DEVELOP A MODEL FOR PREDICTING ILLNESS AND COLD INJURY AND THE ASSOCIATED COSTS IN MAN-DAYS LOST.

THE FEASIBILITY OF USING AFTER-ACTION MEDICAL REPORTS FROM PREVIOUS MARINE CORPS COLD WEATHER EXERCISES TO ESTABLISH A MORBIDITY FORECAST MODEL TO PREDICT NON-EFFECTIVE DAY LOSSES DUE TO COLD MORBIDITY WILL BE EVALUATED. ADDITIONAL SOURCES OF SIMILAR DATA WILL BE IDENTIFIED AND APPRAISED WITH RESPECT TO THEIR CONTRIBUTION TO A MORBIDITY FORECAST MODE. PRELIMINARY MULTIVARIATE ANALYSES WILL BE CONDUCTED ON THESE DATA TO IDENTIFY VARIOUS PREDICTORS ASSOCIATED WITH MEDICAL PROBLEMS FOUND IN COLD WEATHER EXERCISES/OPERATIONS.

EXERCISE TOLERANCE OF DIVERS WORKING AT DIFFERENT DIVE DEPTHS

C. Lundgren, State University of New York, Health Science Center at Buffalo, School of Medicine, Dept. of Physiology, *3435 Main St., Buffalo, New York* 14214 (DN875366)

THE UNITS OF EXERCISE TOLERANCE OF DIVERS WORKING IN THE WATER AT VARIOUS DEPTHS IS NOT KNOWN, THE COMBINATION OF STATIC LUNG LOADING, HIGH GAS DENSITY AND INCREASED AMBIENT PRESSURE IN THE IMMERSED DIVER HAS PROFOUND EFFECTS ON THE DIVER'S MAXIMUM WORK CAPACITY. RESEARCH UNDER THIS CONTRACT IS EXPECTED TO DEFINE THE ACCEPTABLE STATIC LOAD LIMITS FOR THE MOST COMMON DIVER WORK POSTURES. SUCH INFORMATION IS IMPORTANT FOR THE IMPROVED DESIGN OF UNDERWATER BREATHING APPARATUS.

RESEARCH WILL BE CARRIED OUT TO DETERMINE THE EFFECTS OF STATIC LUNG LOADING ON CARDIORESPIRATORY FUNCTION IN SUBMERGED, EXERCISING SUBJECTS AT INCREASED BAROMETRIC PRESSURES. SUBJECTS WILL INITIALLY BE STUDIED IN A SITTING POSITION, EXERCISING ON AN UNDERWATER BICYCLE ERGOMETER, AT DEPTHS OF 15, 60, 120 AND 190 FSW WHILE BREATHING AIR. THE IMPOSED STATIC LUNG LOADS WILL RANGE BETWEEN 20 AND -20 CM H20 WITH REFERENCE TO THE PRESSURE AT THE SUPRASTERNAL NOTCH. MEASUREMENTS WILL INCLUDE MINUTE VENTILATION, TIDAL VOLUME, VITAL CAPACITY, HEART RATE, ECG, ESOPHAGEAL PRESSURE AND POST-WORK VENOUS LACTATE CONCENTRATIONS. SEPARATE DIVES WILL BE CARRIED OUT TO MEASURE PULMONARY FUNCTION PARAMETERS.

EPIDEMIOLOGY OF SCRUB TYPHUS

P.F. Van Peenen, U.S. Dept. of Defense, Uniformed Services University of the Health Sciences, Dept. of Preventive Medicine & Biometrics, *Bethesda, Maryland* 20014 (DD700008)

THE FINAL OBJECTIVE IS PREVENTION OF SCRUB TYPHUS. SUBSETS ARE DEFINING THE ROLE OF CELL-MEDIATED IMMUNITY (CMI) DETERMINING PAST AND CURRENT INFECTION WITH PRECISION AND ACCURACY, AND CHARACTERIZING THE CAUSATIVE ORGANISM BIOCHEMICALLY.

THREE MAJOR LINES OF STUDY ARE FOLLOWED. THE FIRST IS APPLICATION OF CURRENTLY AVAILABLE METHODS FOR QUANTIFICATION OF CMI TO A MOUSE MODEL OF SCRUB TYPHUS. A SECOND APPROACH INVOLVES ANALYSES OF SEROLOGICAL SPECIMENS FROM PATIENTS AND PRESENTLY HEALTHY POPULATIONS, AND IMPROVEMENT OF SEROLOGIC TECHNIQUES USING ANTIGENS FROM RELATED ORGANISMS, INCLUDING ROCHALIMAEA QUINTANA AND THE AGENT OF LEGIONNAIRES' DISEASE. FINALLY, BIOCHEMICAL TECHNIQUES ARE USED FOR PURIFICATION OF ANTIGENS AND FOR UNRAVELLING METABOLIC PATHWAYS FOR THESE RICKETTSIAE AND RELATED BACTERIA.

2.0176,

UNITED STATES URANIUM REGISTRY

B.D. Breitenstein, Hanford Environmental Health Foundation Inc., *P.O. Box 100, Richland, Washington* 99352 (EY-76-C-1837)

The objectives of the U. S. Uranium Registry are to: (1) characterize the exposure of workers to uranium or to radon and its daughters in the front end of the uranium fuel cycle (mining, milling, conversion, enrichment and fuel fabrication); (2) describe and evaluate the efficacy of methods in use in production facilities for monitoring such exposure and, also, radionuclide deposition, including air sampling, urinary bioassay, and lung and whole-body counting; (3) organize the procurement of tissue specimens at autopsy of former workers and conduct the analysis of such specimens to develop d- ta on the deposition, translocation and distribution of uranium in human tissues; (4) survey the status of studies of the health of workers exposed to uranium, radon and its daughters, and confounding nonradiologic hazards in various stages of the fuel cycle, and review relevant literature; and (5) recommend a program of epidemiologic studies to repair important deficiencies in the existing worker health data base and conduct such studies that may be authorized.

Activities of the Registry are carried out by means of a collaborative effort between the Hanford Environmental Health Foundation (HEHF) and the Pacific Northwest Laboratory (PNL) with over-all management by HEHF. Objectives (1) and (2), the characterization of exposure, monitoring and dosimetry in work environments, is accomplished by field visits to relevant facilities of teams consisting of PNL radiological and HEHF industrial hygiene personnel. Field visits to numerous uranium facilities have been accomplished. A review of the regulatory structure of different stages of the cycle and the impact of regulatory policies on personnel protection is nearing completion. The autopsy program is conducted by HEHF contacting companies and their workers and arranging for ultimate donation of the tissues of cooperating workers to the Registry; the analyses will be performed by PNL. An autopsy program will be started at the National Lead Company of Ohio as soon as OMB approval of forms is received. The review of health studies and epidemiologic literature is in progress and is conducted by a team of HEHF and PNL epidemiologists. New studies have not been proposed as yet.

Results to date consist only of a draft progress report of the field studies of facilities relating to objectives (1) and (2).

DETERMINATION OF NORMAL AND HYPERNORMAL CONCENTRATIONS OF ENERGY-RELATED TRACE ELEMENT POLLUTANTS IN THE HUMAN BODY USING TEETH AS AN INDICATOR

L.G. Stang, U.S. Dept. of Energy, Brookhaven National Lab., Dept. of Medicine, *Upton, New York* 11973 (4021)

The immediate goals are to develop and demonstrate a practical, simple, rapid, and inexpensive method for determining and monitoring traces of potentially toxic energy-related elements in the human body. Utilizing this method, concentrations of such elements will be determined in statistically large numbers of individuals with known case histories in order to define existing baseline concentrations of these elements. This will also provide quantitative data needed for determining the relationship between increases above this baseline for given element and parameters (measured by others) such as the health of the individual, the ambient concentration of the element, and occupational factors relevant to energy technology. A longer-range goal is to determine trace element concentrations in deceased populations and compare the results with those from living groups to measure the extent, if any, to which present baseline concentrations for particular elements may already be higher than normal (as determined from the dental remains of individuals who lived prior to environmental pollution from energy-related sources), and to measure the present rates at which these baselines are increasing. The significance of this work is that it develops a convenient basis for indicating the human impact of many energy-related potential environmental pollutants for which even the normal body concentration is unknown.

UNITED STATES TRANSURANIUM REGISTRY

B.D. Breitenstein, Hanford Environmental Health Foundation Inc., *P.O. Box 100, Richland, Washington* 99352 (EY-76-C-1837)

The objective of the USTR is to protect the interests of workers, employers and the public by serving as a national focal point for the acquisition and provision of precise information about transuranics in humans. This is accomplished by the study of the distribution and concentration of transuranics in man through analysis of autopsy tissues of occupationally exposed workers; the evaluation of the estimates of body and/or lung burdens made during the life of an occupational worker for comparison with those based on the analysis of tissues obtained after death; seeking histopathologic changes in autopsy tissues that might be attributed to the effects of transuranics; and the study and comparison of findings in animal experiments with transuranics and those in human beings who have transuranic depositions.

The approach of the Registry program relies entirely upon securing samples of various organs at autopsy of occupationally exposed personnel. In order to obtain the greatest benefit it is necessary to identify the maximum number of occupationally exposed transuranium workers, past and present; obtain medical and health physics releases; secure pre-arranged autopsy permission and at autopsy secure appropriate tissue samples for pathological examination and analyses of transuranium element content. The organs are selected according to whether the estimated deposition at the time of death is greater or less than 50% of the maximum permissible systemic burdens as listed in ICRP publication II. Prosectors have been identified and are used to assist the pathologist in obtaining the desired samples and to assure proper identification and to prepare additional histological slides. Also, the prosectors verify weights, trim and prepare samples for processing by the analytical laboratories.

The USTR has 849 valid autopsy releases through 1979. There have been 136 autopsies obtained, of which 89 autopsy analyses have been completed. In addition, there are 6 consents for whole body donations. Currently there is one whole body donations. Currently there is one whole body donor in analysis. This is an important case because it is the first whole body analysis from an occupationally exposed worker who was estimated to have more than a maximum permissible body burden of americium.

The DOE operating sites which have been actively participating include Hanford, Rocky Flats, Los Alamos Scientific Lagor (Text Truncated - Exceeds Capacity)

GASIFIERS IN INDUSTRY--UMD PROJECT: POLLUTANT CHARACTERIZATION

K.E. Cowser, U.S. Dept. of Energy, Oak Ridge National Lab., Central Management Office, *P.O. Box X, Oak Ridge, Tennessee* 37830 (2943)

The objective of this program is to implement an environmental and health, monitoring and testing program at the University of Minnesota at Duluth Gasifier Project. Process streams, plant effluents, and the working environs will be characterized chemically and physically by on-line and in-plant sample collections, measurements, and monitoring. Data developed will be used to guide subsequent bioassays and ecological testing of samples, to correlate possible worker exposures, and to assess the potential health and environmental impacts of this demonstration facility.

SAFETY PLANNING FOR POPULATIONS NEAR NUCLEAR INSTALLATIONS

C.V. Chester, U.S. Dept. of Energy, Oak Ridge National Lab., Health Physics Div., Emergency Technology Section, *P.O. Box E, Oak Ridge, Tennessee* 37830

Consequences of accidental releases of radioactive materials from facilities in the nuclear fuel cycle are analyzed. The primary objective of the work is identifying methods of reducing the impact on the civilian population. Emergency measures after the release as well as changes in the facilities to reduce the probability and magnitude of a release are studied and recommendations made.

RESULTS: Inhalec dose and deposition from catastrophic accidents to stored spend fuel elements and surface-sited, high-level waste tanks have been estimated. The dose and deposition from released material are calculated using real-time varying meteorological data. Underground siting of LWR plants is being studied.

OCCUPATIONAL HEALTH PROBLEMS IN FOSSIL ENERGY DEVELOPMENT

Unknown, Flow Industries Inc., *21414 68th Ave. S., Kent, Washington* 98031

Technical assistance is being provided to assure that possible health and safety problems associated with innovative fossil fuel technologies are identified and dealt with. Pilot plant programs and activities were reviewed. Available literature and data were reviewed to assess the toxic, carcinogenic, and other hazardous components for which standards or data exist. Site visits were made to energy research centers and pilot plants. The results will be used to recommend approaches to occupational health. A manual workbook for health and safety matters in fossil energy plants is being prepared. Investigation of existing occupational health and safety activities has included acquisition of published and unpublished materials, development and distribution of a questionnaire, and site visits. Two reports have been submitted. One report concludes that existing programs tend to stress safety more than health and to emphasize compliance and control of hazards. Consequently, most health and safety data currently available are not ideal for epidemiological surveillance. The other report describes possible methods of linking data, of follow-up for mortality studies, and of constructing work histories or exposure data. In the second phase, methods for epidemiological linkage of data were developed. The specific problems of linking morbidity indicators with work or exposure patterns were addressed. It was found that potential health problems could be categorized into three causal types: general industrial, coal related, or associated with high-temperature and high-pressure processes. Each hazard level was related to levels of program control in four main health and safety activities. From this, recommendations were developed for recordkeeping, for health and medical programs, and for industrial hygiene practices. A detailed outline for health and safety workbook has been submitted.

CHROMOSOME STRUCTURE AND FUNCTION

L.L. Deaven, U.S. Dept. of Energy, Los Alamos Scientific Lab., Cellular & Molecular Biology Group, *P.O. Box 1663, Los Alamos, New Mexico* 87544 (000219)

The transition of normal cells into the malignant state is frequently accompanied by increased variability in chromosome number and structure. Treatment of in vitro cell cultures with clastogenic agents can also result in clonal populations with altered karyotypes. Whether karyotype instability is cause or an effect of malignant transformation its general association with transformed phenotypes makes it a relevant end point for energy-related toxicants. We are examining energy-related pollutants of the shale oil industry for their clastogenic properties and for their potential to transform cells into clonal populations with altered karyotypes. Initial studies utilize known components of oil shale applied to in vitro Chinese hamster cells (line CHO). These results are then related to complex mixtures of materials generated by oil shale extraction. Materials with clastogenic potential, as determined by the CHO studies, will then be applied to human lymphocytes and/or fibroblasts in vitro. Materials which are clastogenic or which induce elevated levels of sister chromatid exchange at relatively high concentration will then be tested at expected environmental and/or physiological levels. Eventually, when available, selected individuals with known exposures will be examined for chromosome damage in peripheral lymphocytes.

ANALYSIS OF THE HUMAN HEALTH AND ECOLOGICAL CONSEQUENCES OF PLUTONIUM AND OTHER TRANSURANICS

J.W. Healy, U.S. Dept. of Energy, Los Alamos Scientific Lab., *P.O. Box 1663, Los Alamos, New Mexico* 87544 (000899)

As a fuel for breeder reactors, plutonium promises to extend the uranium resources by many times and could be important in the coming energy shortage. However, public concern over its carcinogenicity has caused difficulties in such use and, in some cases, questions have been raised which were difficult to answer because the data available had not been collated and made available in a useful form. This project provides analysis of existing information to give summaries of the present data important to a given objective. It is anticipated that eventually these reviews and conclusions will be incorporated into an analysis of the total health hazards from the use of plutonium. A second objective is to provide a body of trained people to answer DOE problems involving the health effects of plutonium. A critical review of available data revealed the importance of differing experimental techniques and an increased uptake of these elements compared to plutonium. A detailed review of the first draft of an EPA standard on plutonium in soils was made at the request of DOE which revealed many technical and sociological difficulties that were discussed with EPA personnel, as well as transmitted to DOE in letters. A limit for shallow earth burial of materials contaminated with transuranic elements is being derived currently.

MOLECULAR PERTURBATIONS IN MAN CAUSED BY ENERGY-RELATED POLLUTANTS

N.G. Anderson, U.S. Dept. of Energy, Div. of Biological & Medical Research, *9700 S. Cass Ave., Argonne, Illinois* 60439 (002454)

The objective is to develop and validate new techniques for measuring the carcinogenic, mutagenic, and toxic effects of energy-related pollutants on human populations. The new technique of protein gene product (PGP) mapping allows most of the estimated 30,000 to 50,000 PGPs (human cell building blocks) to be seen analytically. Different cells characteristically contain different sets of PGPs. In cancer the PGP population of a cell changes, and PGP mapping raises the possibility of early cancer detection, cancer typing, and assessment of therapy effectiveness. PGP mapping also detects about 1/3 of amino acid substitutions resulting from mutations and makes possible measurement of the background mutation rate in man, the detection of changes in that rate, and the detection of genetic disease-causing mutations in individuals. Toxic agents cause living cells to leak PGPs and other cell constituents. With PGP mapping, cell type markers may be identified and used as indicators of specific organ damage. Commercially available, clinically useful ISO-DALT mapping system is expected in three years. Commercial sales of systems and products evolved from this program are now over 100 million dollars per year (zonal centrifuges, vaccine centrifuges, centrifugal analyzers, vaccines, reagents, etc.).

HEALTH EFFECTS IN THE PETROLEUM INDUSTRY

E.L. Alpen, University of California, Central Office, Lawrence Livermore Lab., *P.O. Box 808, Livermore, California* 94550 (002692)

There exists a large population of individuals who are routinely exposed to low levels of volatile hydrocarbons during their occupationally related activities in the petroleum industry. Although it has been known for many years that some of these compounds are carcinogenic, and that they may also cause other unrelated injury to organ systems, little or no specific attention has been paid to analyses of disease rates among these workers. There are, as yet, poorly defined reports that there is an elevated cancer mortality rate in Contra Costa County in California, a major refining center. We are proposing to study the epidemiology of a number of disorders,

concentrating at first on cancer and cardiovascular and respiratory disorders among refinery workers. The study would be based in the beginning on the Contra Costa population.

IVEP-HEALTH EFFECTS
L. Anspaugh, University of California, Central Office, Lawrence Livermore Lab., *P.O. Box 808, Livermore, California* 94550 (RPIS-2336)
The objective is to determine potential health effects associated with the development of geothermal resources, with emphasis on the Imperial Valley. Work will be carried out through a subcontract with the California Department of Health to (1) examine available effluent data and health effects data to determine relevant damage functions or to specify needed effects research; (2) establish a system for the rapid reporting of mortality and morbidity in Imperial County; (3) review occupational health programs and provide recommendations; and (4) conduct special surveys to determine the public's perception of odor annoyance and health problems. The results expected are: (1) predictive assessment of health effects from geothermal resource development; (2) early warning system to detect actual health effects should they occur; and (3) quantitative surveys of odor annoyance due to hydrogen sulfide.

EVALUATION OF CARBON MONOXIDE IN BLOOD SAMPLES FROM THE SECOND HEALTH AND NUTRITION SURVEY
E.P. Redfor, University of Pittsburgh, Graduate School, *1028H Cathedral of Learning, Pittsburgh, Pennsylvania* 15213 (007590)
This is a continuation of a study of carbon monoxide (CO) in the blood of human subjects participating in the Second National Health and Nutrition Survey (HANES II), a detailed study of health indicators in sample populations of many communities throughout the US. The purpose of this aspect of the survey is to evaluate the levels of blood carboxyhemoglobin in over 6,000 normal individuals of all ages in typical US communities, from whom accurate histories and clinical studies are available. Two main results are anticipated from this work. First, values from nonsmokers will indicate the extent to which absorption of CO from community air pollution is present in the US. Second, the data will provide an objective measure of current inhalation exposure to tobacco smoke in smokers, an important addition to clinical evaluation of health effects from smoking.

US URANIUM REGISTRY
B.D. Breite, Hanford Environmental Health Foundation Inc., *P.O. Box 100, Richland, Washington* 99352 (003182)
The U.S. Uranium Registry will provide centralized collection and analysis of data on the exposure and estimated deposition of uranium and radon daughters among exposed workers and investigate the effects of these nuclides on the health and mortality of workers in the uranium mining, milling, enrichment, and fuel fabrication industries. Insufficient attention has been devoted to the study of the health of workers exposed to uranium in the nuclear industry. The mining and further processing of uranium will increase as a result of the current emphasis on nonproliferation nuclear cycles. This expansion of the uranium industry, estimated in 1976 as a 25-fold increase in uranium mining and milling and a 15-fold increase in fuel fabrication facilities, increases the urgency of defining as thoroughly as possible the potential health effects that might be anticipated in various segments of the industry. The results of the activities included in the Uranium Registry could be a major contribution to setting standards for exposure of workers to uranium. It can also assist in the identification of work assignments or process steps that are major sources of uranium exposures of workers and, therefore, should be given high priority for the development of control procedures.

HUMAN HEALTH AND ENERGY PRODUCTION
D. Grahn, U.S. Dept. of Energy, Div. of Biological & Medical Research, *Chicago, Illinois* (000811)
Causes of death in man are sensitive to socio-economic, cultural, occupational and general environmental pollutant variables. This project is therefore designed to identify the contribution of each factor to the age and cause of death, to quantify its effect and to develop predictive models for impact analysis of energy facility sites and regions of resource development. The models should permit reevaluation of other cause-effect studies of air pollution and human health and the development of a rational cost-benefit analysis of health effects vs. effluent control technology. The study will utilize existing data bases such as the U.S. vital statistics, census data, commercial and industrial activity data. Standard methods of demographic and life-table analysis will be employed to isolate specific relationships between health effects and socio-economic, etc., factors. The methods of multiple regression and factor analysis will also be employed. Wherever possible we will use data bases existing in our own and other DOE facilities. Major factors such as education, income, occupation, migration account for 30% to 60% of variation in age standardized death rate. Demographic projection models have been developed to estimate effects of radioactive and non-radioactive pollutants on life expectancy, cause and rate of mortality.

U.S. TRANSURANIUM REGISTRY OF DOE CONTRACTOR AND LICENSEE EMPLOYEES
J.A. Nororo, Hanford Environmental Health Foundation Inc., *P.O. Box 100, Richland, Washington* 99352 (000409)
The U.S. Transuranium Registry was established in 1968 to study the internal deposition of transuranic elements in workers occupationally exposed to these substances. An important aspect has been to compare transuranic deposition estimates made during life with tissue distribution and concentration in autopsy specimens. Investigation of the health status, longevity and causes of death among transuranic workers is also a goal of the registry. Fourteen thousand transuranium workers have been identified at DOE contractor and NRC licensee plants; 855 prearranged autopsy permissions have been obtained and 66 autopsies completed. In general, smaller systemic and larger lung depositions of plutonium have been found than were predicted by antemortum health physics estimates. Efforts are in progress to increase participation in the USTR by sites employing transuranic workers, and to improve autopsy procedures and tissue preparation.

METABOLISM AND EFFECTS OF INTERNALLY DEPOSITED RADIONUCLIDES AND TRACE ELEMENTS
A.F. Stehney, U.S. Dept. of Energy, Argonne National Lab., *9700 S. Cass Ave., Argonne, Illinois* 60439 (000302)
The objective is to determine the long-term effects of radium, thorium, and other internal emitters in humans. Epidemiological and clinical studies of human beings who have been occupationally or iatrogenically exposed to intake of alpha-emitting radionuclides will be undertaken. Medical and dosimetric data are obtained by study of living persons and autopsy material and from medical records. The principal end-points are mortality by cause, neoplasms, and pathological changes in bone and lung. Whole body counting (in vivo), radiochemistry, and microscopic techniques are employed. Expected results include identification of diseases associated with internally deposited radionuclides and determination of quantitative relationships between dose and effect. These results are needed for assessment of risk from radionuclides in nuclear fuel cycles.

DOSE REASSESSMENT FOR POPULATIONS ON RONGELAP AND UTIRIK FOLLOWING EXPOSURE TO FALLOUT FROM THE BRAVO INCIDENT (MARCH 1, 1954)
J.R. Naidu, U.S. Dept. of Energy, Brookhaven National Lab., *Upton, New York* 11973 (3010)
Incidences of thyroid nodules, benign and malignant, in the exposed populations of Utirik and Rongelap have indicated critical differences in correspondence between nodule incidence and thyroid dose for the two populations. The estimated external dose received from the time fallout began to the time of evacuation shows that the Rongelap population received an external dose (175 rads) which was about thirteen times that for the Utirik population (14 rads), and the thyroid dose was about ten times larger, whereas the incidence of thyroid nodules in the two

populations were not significantly different. A preliminary study has indicated that the critical area of investigation that could shed light is the period during fallout and evacuation for both the islands. In addition, the fact that the Utirik population returned within 120 days following evacuation, whereas the Rongelap population returned only after three years, requires that we look closely at the Utirik population in terms of a longer period, both internal and external. Further studies would, therefore, have to concentrate on the re-examination of all available data in reports issued by various agencies during that period, consultations with uncertainty, and using appropriate computer programs to analyze the data. The end result will enable us to look for correlations between the incidence of thyroid nodules and the reassessed dose estimates.

SOMATIC CELL CHROMOSOME CHANGES IN HUMANS EXPOSED TO 239-PLUTONIUM AND 222-RADON

W.F. Brandom, University of Denver, School of Arts & Sciences, Dept. of Biological Sciences, *2115 S. University Blvd., Denver, Colorado* 80210 (7049)

The objective of our study was to determine whether a biological response related to estimated physical doses could be observed in uranium miners' or plutonium workers' cells. If a biological dose-response was observed, the somatic cell chromosome test could provide biological indicator of a toxicological problem and supplement other indications for setting permissible radiation protection standards. The test system used was the prevalence of chromosome aberrations (dicentrics, rings, inversions, translocations, and deletions) in peripheral blood lymphocytes of controls and uranium miners and plutonium workers, plotted against estimated physical radiation doses. Biological respones in the relative prevalence of chromosome aberrations are observed in uranium miners' and plutonium workers' cells. The analysis to date indicates that estimated lung burdens in the plutonium workers are more significant in affecting lymphocyte chromosomes than current estimated systemic burdens. In the future, it is expected that somatic cell chromosome aberration frequencies will be used in conjunction with physical dosimetric measurements to screen other populations exposed to low levels of ionizing radiation.

EXPOSURE TO EXTERNAL INTERNAL & RADIATION - LOW-LEVEL PLUTONIUM, TRANSPLUTONIUM & FISSION PRODUCTS & OTHER ELEMENTS STUDIES

C.W. Mays, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Anatomy, *1400 E. 2nd S., Salt Lake City, Utah* 84112 (000445)

The objectives are: (1) evaluation of the retention, distribution and dosimetry of internally deposited radionuclides; (2) prediction of the radiation risk to humans from occupational and environmental exposure; (3) safe removal of radionuclides from the body; and (4) assistance to US DOE and other organizations on questions of the risk to man from radiation, especially plutonium.

HEALTH AND MORTALITY STUDY

E. Tompkins, Oak Ridge Associated Universities Inc., *Box 117, Oak Ridge, Tennessee* 37830 (002493)

The objective of the DOE health and mortality study is to evaluate, on a continuing basis, the disability and mortality experience of persons with a history of employment in selected installations associated with the nuclear industry. The primary purpose of the study is to determine if such employment histories are associated with an increase in age- and sex-specific mortality in general, or with an increase in age- and sex-specific mortality due to selected causes of death. Some determinant factors to be studied are: the adequacy of comparison populations to predict the expected mortality experience of the defined study population; the type, level, and dose rate of radiation exposure of the study population; and the length of time elapsed from first employment in a nuclear industry to morbidity and mortality.

THE INFLUENCE OF LATE RADIATION EFFECTS ON THE IMMUNOLOGIC PARAMETERS OF AGING

T. Makinodan, University of California, Los Angeles Campus, School of Medicine, *2025 Zonal Ave., Los Angeles, California* 90024 (007591)

Special emphasis will be placed on the development of methods which can be applied to the study of monozygotic and dizygotic twins where both were exposed, where neither were exposed, and where only one was exposed to radiation. Preliminary studies will be carried out with Hiroshima immigrants who immigrated to the U.S. before 1940 and their Japanese-American descendants in the Los Angeles area. This proposal includes provisions for assisting in the development of competent investigators and laboratory facilities at the Radiation Effects Research Foundation (RERF) in Hiroshima and Nagasaki.

ASSESSMENT AND CONTROL OF RADIOACTIVE AIR CONTAMINANTS

A.J. Breslin, U.S. Dept. of Energy, Office of Health & Environmental Research, Environmental Measurements Lab., *376 Hudson St., New York, New York* 10014 (000732)

The exposure of man or woman and his or her environment to airborne radioactive substances is studied in terms of the successive steps from sources via environmental pathways to ultimate sites of deposition, including the respiratory tract. Particular attention is being given to public exposure to background radon and radon daughters. The long range objectives of these investigations are to improve capabilities to assess, monitor, and control contaminants in public and occupational environments.

DETERMINATION OF PLUTONIUM IN MAN

J.F. McInroy, U.S. Dept. of Energy, Los Alamos Scientific Lab., *P.O. Box 1663, Los Alamos, New Mexico* 87544 (000380)

This project will establish statistically significant measurements of the base-line concentrations of environmental plutonium in the general population of geographic areas of interest to the DOE, monitor those areas where the base line has been established to determine if changes have occurred, measure the tissue distributions of plutonium in occupationally exposed workers, determine the particle size distribution of plutonium oxide aerosols in tissues of occupationally exposed workers, and evaluate the histological effects of deposited plutonium on the tissues of exposed workers. Methods utilized include collecting organs of interest from autopsies; recording pertinent epidemiological information; analyzing quantitatively for plutonium and normalizing the results to a concentration value; and statistically evaluating the distributions.

MEDICAL STUDIES OF THE PEOPLE OF THE MARSHALL ISLANDS ACCIDENTALLY EXPOSED TO FALLOUT

R.A. Conard, U.S. Dept. of Energy, Brookhaven National Lab., *Upton, New York* 11973 (000032)

The primary objective is the determination of the lifetime effects of fallout radiation on the Marshallese who were accidentally exposed to radioactive fallout on March 1, 1954. Medical surveys of these people are conducted at quarterly intervals, and an unexposed Rongelap population is examined for comparison. The surveys, carried out jointly by Brookhaven National Laboratory under the auspices of the Department of Energy, and the Trust Territory of the Pacific Islands, are of great importance in view of the development in this population of growth impairment in some exposed children, thyroid lesions, and one case of acute leukemia.

BIBLIOGRAPHIC REFERENCES: Conard, R.A., Summary of Thyroid Findings in the Marshallese 22 Years After Exposure to Radioactive Fallout, Radiation-Associated Thyroid Carcinoma, L. DeGroot (ed.), pp. 241-257, Grune and Stratton, New York, 1977.

INDOOR AIR POLLUTION EPIDEMIOLOGY STUDY

C.D. Hollowell, University of California, Berkeley Campus, Lawrence Berkeley Lab., *Berkeley, California* 94720 (001866)

The broad goals of this project are: (1) to characterize indoor air pollution; (2) to identify the important sources, abundance, and fate of indoor air pollutants; (3) to study the abatement of indoor air pollutants; (4) to characterize exposures of the occupants to the important air pollutants; (5) to study the health and welfare effects; and (6) to assess the impact of various energy-conservation strategies on indoor air quality. The epidemiological work will concentrate on the nitrogen oxides, with careful attention being paid to all other air pollutant species which can be characterized. Results of the study indicate that levels of gaseous and respirable particulate air pollutants in the indoor environment frequently exceed the levels commonly found in the outdoor urban air. Levels of CO and NO/sub 2/ were found to exceed existing and recommended ambient air quality standards. Such findings indicate a potential impact of combustion-generated indoor air pollution on human health, and if borne out by further work they may ultimately have a large impact on energy conservation strategies for buildings, on the future design of epidemiological studies, and on the need for more stringent control of air pollution from indoor combustion sources.

DOSIMETRY FOR HUMAN EXPOSURE

G.D. Kerr, U.S. Dept. of Energy, Oak Ridge National Lab., *P.O. Box X, Oak Ridge Operations Office, Oak Ridge, Tennessee* 37830 (00801)

The objectives of these studies are to improve the physical dosimetry of human radiation exposures and the assessment of radiation exposure risks to man. Total cancer risks from mixed neutron and gamma-ray exposures are being investigated using data from animal studies and data from human epidemiological studies. These studies will provide an improved basis for making sound judgments regarding radiation protection against neutrons at current fission power reactors and future fission power reactors. Mathematical models and computer codes are developed to investigate radiation dose--biological effect relationships. Extensive use is made in these studies of the vast medical and epidemiological studies of the Japanese atomic-bomb survivors which constitute the most extensive source of data on the latent effects of human exposure to gamma rays and neutrons. The studies have provided the first accurate assessment of dose to bone marrow and risk of leukemia from neutron exposures. Estimates of other cancer risks from neutrons will be made, and estimates of total risk of leukemia and other cancers will be used to review the adequacy of current radiation protection criteria and monitoring practices for neutrons.

EVALUATION OF INTERNALLY DISTRIBUTED KRYPTON-85 AS A HEALTH HAZARD
S.H. Cohn, U.S. Dept. of Energy, Brookhaven National Lab., *Upton, New York* 11973 (001373)
The emission of krypton-85 (Kr-85) from nuclear reactors constitutes a potential radiation hazard to an exposed population. The hazard is due not only to external radiation but also to internal radiation following exposure to and inhalation of the gas. To evaluate the degree of the internal radiation hazard, it is necessary to know several biological parameters of behavior of Kr-85 in human beings. Estimation of radiation dose requires that the rate of reaching tissue equilibrium concentrations of Kr-85 be determined. The objective of this study is to determine the partition coefficients for Kr-85 into human tissues as well as their saturation and desaturation rates. It is proposed to measure these biological parameters in up to 15 normal healthy subjects after inhalation of tracer amounts of Kr-79. The BNL whole body counter will be used to follow the uptake, distribution and excretion of the inhaled Kr-79. The pharmacokinetics of Kr-79 will be examined by computer analysis based on respiratory parameters of each individual. Dosimetry data were used to better define the radiation hazard from the fission product Kr-85. Since Kr is known to be soluble in body fat, the effect of adiposity on the uptake and retention of Kr-79 was evaluated in subjects representing a wide range of body fat.

COAL-RELATED DISEASE DETECTION
K. Hubner, Oak Ridge Associated Universities Inc., *Box 117, Oak Ridge, Tennessee* 37830 (001928)
It is proposed to study occupational diseases associated with the coal industry, particularly chronic lung diseases. The methods used will be nuclear medical procedures to evaluate subtle and obvious changes in lung function and cytologic techniques on sputum, to evaluate premalignant changes and to detect early malignancy. Emphasis will also be placed on chronic obstructive pulmonary disease. In addition to work on black lung disease the program will examine methods of detecting minimal effects on workers exposed to polynucleated aromatic hydrocarbon in an operational coal liquefaction pilot plant. The possibility of using cytogenetic technology will be investigated. The potential for using positron emitters with a computerized transaxial tomograph will be investigated.

EPIDEMIOLOGICAL STUDY OF PLUTONIUM WORKERS
J.H. Stebbings, U.S. Dept. of Energy, Los Alamos Scientific Lab., Health Div., *P.O. Box 1663, Los Alamos, New Mexico* 87544 (001879)
Past and present plutonium workers from major United States nuclear installations will be followed to determine age-specific mortality rates from all major causes of death, with special emphasis upon cancer. Dose-response relationships will be estimated using systemic body burden data from urine tests. The study population, approximately 20,000 individuals, will include all workers with estimated body burdens above one nanocurie, random samples of exposed workers with lesser or no body burdens, and random samples of non-exposed workers from the same installations. A subset of 8000 workers will be actively followed and questionnaire studies of personal risk factors and of morbidity from cancer, cardiovascular, chronic respiratory, and other chronic diseases will be carried out. Related studies in progress include a clinical study of 26 Manhattan District Project workers, studies of cancer incidence and mortality in residents of Los Alamos, New Mexico, and a preliminary follow-up study of mortality in the most highly burdened plutonium workers.

ASSESSMENT OF HEALTH EFFECTS OF ENERGY SYSTEMS
M. Goldman, University of California, Davis Campus, School of Medicine, Dept. of Medicine, *Davis, California* 95616 (002923)
Assessment of risks to health from energy-related pollutants are required to meaningfully estimate the environmental cost/risk/benefit tradeoffs involved in development of energy resources and production technologies. The risk assessment program at the Radiobiology Laboratory utilizes three levels of effort: (1) acquisition and storage of relevant data, (2) gathering of mathematical and statistical methods useful in assessing risks, and (3) analysis of data using existing methods or by new techniques. Emphasis will be placed on determining the validity of models relative to pollutant exposure modalities (e.g., single, acute exposures vs. chronic exposures). Emphasis will also be placed on assessing decremental effects on health other than mortality and tumorigenesis. Our literature review of health effects of pollutants from fossil-fuel power generation (published as an annotated bibliography) made clear that the available animal data, needed to scale effects to humans, are not always in the best form. Such data will require extensive effort before they can be properly utilized to assess risks. We have chosen the coking industry as a surrogate for future planned coal conversion plants. The similarities between fugitive emissions, characterization and monitoring are significant and germane to new conversion methods. This research will build on the experimental data base and models evolved to relate to information obtained on coke oven workers and their health status following high level exposures to develop models for lower level exposure assessment to possible impacted members of the general population.

DETERMINATION OF 239-PU CONCENTRATIONS IN NEW YORK CITY AUTOPSY TISSUE SAMPLES
M. Eisenbud, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016 (7156)
Now that the methodology for the assay of plutonium in tissue samples has been developed to optimum state-of-the-art accuracy and precision, we propose to continue making these measurements at an accelerated rate during the coming year. Our proximate goal is the determination of the Pu-239/Pu-240 concentrations in the bone, lymph nodes, lung, liver and kidney of each of 50 cases of accidental death occurring in residents of the New York City area. In addition to measurement of plutonium and stable calcium in these samples, we will attempt to determine, in a limited subset of these samples, the content of other manmade and natural radionuclides when sample size permits. These other alpha emitters in order of priority include Am-241, Th-(alpha emitters) and, when possible, Pb and Po-210. From this information, and from the trace metal contents previously determined, we hope to examine models relating source terms to body burden thereby providing estimates of the variation of internal burdens of these materials as a function of their content in the environment. In addition, we will be able to examine transport models of these materials in the environment and their metabolism and kinetics in the body. Finally, we wish to establish accurate baseline values for these radionuclides in the body to act as a reference point for assessing the impact of increased sources of intake. Analysis of fallout plutonium is essential in defining those parameters used to estimate the transfer of plutonium from the environment to humans. In order to assess the temporal change in Pu alpha content of human tissues, additional tissue samples may be collected during the year.

RESEARCH ON HUMAN GENETICS IN ICELAND
S. Fridriksson, Iceland Genetical Committee, *Reykjavik, Iceland* (006208)
The Icelandic demographic data are being used for various hereditary and social studies. The data consist of some 313,000 birth records covering the whole nation from 1840 as well as marriage records, the national registry, and death records. A large number of individuals have been manually linked into families. A program for arranging all the data on an IBM 370 Model 30 computer has been proposed. To the demographic data are added various information about the individual, such as blood groups, various proteins, diseases and disabilities, and cause of death. Karyotypes of over 900 individuals have also been analyzed. In a collaborative effort by various institutes, 135 first-cousin marriage families have been analyzed for chromosome linking of various genetic markers and possible inheritance of various characteristics. A study of familiality of breast cancer was continued and an investigation was started on a possible family aggregation of ischemic disease in Iceland. A study of assortative mating was carried out in relation to intelligence as indicated by mean score achieved at final examination from elementary school. Furthermore, the relation between mean scores of parents and children was investigated and the relation between intelligence and mental health was studied by comparing these records with the psychiatric register.

ERDA HEALTH STUDY, CHRONIC RADIATION EXPOSURE - CORRELATION OF RADIATION EXPOSURE WITH BIOLOGICAL EFFECT
C.W. Kirklin, Hanford Environmental Health Foundation Inc., *P.O. Box 100, Richland, Washington* 99352 (000408)
This project is to determine the long-range effect of low-level long-term occupational radiation exposure on man. The Department of Energy Richland Location (DOE-RL) Contractors employees' health, radiation exposure, and job assignment records have been compiled and organized in a data file dating from 1944. This, with other data, is being studied to develop relationships between radiation exposure and mortality. Data accumulation includes (1) employee identification data, (2) employment history, (3) sibling control groups, (4) occupational radiation exposure (internal and external), (5) medical x-ray exposure, (6) medical examination data, (7) environmental exposure other than radiation, and (8) mortality data.

SIMS THREE YEAR STUDY ON STATISTICS AND ENVIRONMENTAL FACTORS IN HEALTH
D.L. Thomsen, Society for Industrial & Applied Mathematics, *97 Parish Rd. S., New Canaan, Connecticut* 06840 (007134)
SIMS will continue to coordinate the study with respect to publication and communication and will also maintain appropriate liaison with the review panel, the first meeting of which was held October 1976 together with members of the Columbia and Stanford groups. The object of the Columbia University group

is to develop statistical methods and models for describing the effects of the environment, measured by pollution and weather variables, on respiratory diseases. Work in the following areas is underway: alternatives to multiple regression, time series models, methods for detecting clusters of cases, measuring pollution levels for an entire geographic area, and the association between air pollution and mortality. The Stanford University group has been investigating the time and space variability of pollutant concentrations. Topics of investigation have included maximum concentration of a pollutant concentration time series as related to the maximum of a subseries, spatial autocorrelation of station measurements, interpolation of pollutant concentrations between monitoring stations, and relation of geographic distribution of a mortality or morbidity index to the distribution over the same geographic region of an index of air pollution.

INHALATION HAZARD TO URANIUM MINERS

F.T. Cross, U.S. Dept. of Energy, Battelle Pacific Northwest Lab., *P.O. Box 999, Richland, Washington* 99352 (000393)

The objective is to determine the agents or combinations of agents and their levels that are responsible for the high incidences of severe respiratory disease such as pneumoconiosis, emphysema, and carcinoma that are reaching epidemic proportions in uranium miners. Experimental studies have resulted in pulmonary fibrosis, severe emphysema, and bronchiolar-alveolar and squamous carcinoma in rodents and beagle dogs that receive daily exposures to radon daughters and uranium ore dust, with and without concomitant cigarette smoking. Continuing studies are designed to: (1) define the possible contributing pathogenic roles of uranium ore dust and cigarette smoking; (2) provide reliable data to relate exposure dose to absorbed dose; (3) determine effects of altered dose-rate on carcinogenesis; and (4) measure the relative effectiveness of altered radon daughter attachment fractions and ratios upon induction of severe respiratory disease to determine whether the working level concept may not be both inadequate and dangerous in evaluation of inhalation hazards of present and future uranium mining operations.

ASSESSMENT OF BIOMEDICAL AND ENVIRONMENTAL COST OF ENERGY SYSTEMS

L.D. Hamilton, U.S. Dept. of Energy, Brookhaven National Lab., *Upton, New York* 11973 (000756)

This program aims at developing a systematic overview of biomedical and environmental costs of energy production and use. All forms of energy are being considered. Starting with a compilation of residuals from the energy system, the various pathways to man are traced. This task entails definition of transport mechanisms including chemical conversions and various links through the biosphere to man. An evaluation is then made of effects. The initial focus is on biomedical effects and environmental effects on animals, crops, other vegetation, and on land, known to affect man. This evaluation relies on available information; epidemiological data, field and laboratory studies carried out on appropriate animals and vegetation, and basic biomedical research designed to elucidate molecular and cellular mechanisms underlying biological responses to various residuals. By taking account of the magnitude of energy flow through the system and of the population exposed, total effects are calculated. The basic framework of the evaluation is provided by the national energy system models and data base in use and under development by the Brookhaven National Laboratory (BNL) Energy Systems Analysis Group (ESAG). That work provides a significant resource for this program and a means of integrating the results of the program into national energy policy analysis.

ESTABLISHMENT OF THE HIGH RISK POPULATION LABORATORY

R.F. Heber, University of Wisconsin, Madison Campus, Mental Retardation Research & Training Center, *1815 University Ave., Madison, Wisconsin* 53706

OBJECTIVES: Establishment of a High-Risk Population Category (Milwaukee Project) is a longitudinal study of the prevalence of mental retardation in a depressed urban area and the effects of a comprehensive rehabilitation program in preventing mental retardation.

METHODOLOGY: 1. The high-risk population laboratory was established with the aid of a door-to-door survey conducted in an area of metropolitan Milwaukee which had been previously identified as having an extremely high prevalence of retardation. 2. All members of the survey family, both children and adults, received an individual intellectual appraisal in addition to receiving several experimental learning and language tests. In addition, extensive data was obtained on family, social, education, and occupational history and status. 3. From this population pool samples are selected with the characteristics required by the individual studies being undertaken by the 'high risk' population laboratory. 4. The population laboratory survey, over a period of a year, contacted all women residents in the area at the time of child birth. All family members were subsequently individually evaluated when the mother was suspected of retardation on the basis of post delivery intellectual screening. This has made accesible a substantial number of mentally retarded young adults and their offspring.

FINDINGS TO DATE: The data derived from the project during the current grant period further extends previously reported data which indicated that the high prevalence of mental retardation found among disadvantaged population group is accounted for, largely, by relatively small proportions of the population involved. (This research approach was initially established as a unique focus of the research program of the Center when little knowledge was available about the relationship of poverty to mental retardation.) Based upon this accumulated data, results show that the use of comprehensive rehabilitation of high risk families, families with a high prevalance of mental retardation, must be deemed a successful approach to the prevention of mental retardation. Families have been followed for over ten years. The children of the treated group show no retardation and in fact no child at ten has an IQ below 85, compared to the control where 60 percent are below 85. (Text Truncated - Exceeds Capacity)

HOMOCYSTINURIA - METHIONINE METABOLISM IN MAMMALS

S.H. Mudd, U.S. Dept. of Health & Human Services, Public Health Service, Alcohol Drug Abuse & Mental Health Admin., National Inst. of Mental Health, Alkaloid Biosynthesis Section, *Bethesda, Maryland* 20014 (Z01 MH 00936-16 LGCB)

A survey of the health status of parents and grandparents of cystathionine synthase deficient patients is being continued. The aim is to determine whether heterozygotes for this genetic defect are at increased risk for coronary artery disease. By appropriate physician contact we have now been able to obtain responses from more than 190 families with homocystinuric patients, 113 with new-mutation achondroplastic dwarfism, 125 with hyperphenylalaninemic, and 35 with cystinotic children. Most of the information has been entered in a computer and a preliminary analysis carried out. This preliminary analysis suggests that the questionnaire approach has yielded valid data since the findings in the control groups are reasonable in comparison with data obtained in more elaborate epidemiological studies. It appears, also, that interpretation of the data will be made more rigorous by (a) addition of further control families (b) documentation of the ages at which initial coronary attacks occurred in fathers who have had non-fatal attacks of this kind, and (c) obtaining approximate years of birth and death for grandparents for whom such dates are not known exactly. Efforts to obtain such information are now underway.

THE OFFSPRING OF SCHIZOPHRENICS - MARKERS OF A SCHIZOPHRENIC DISPOSITION

R.O. Reider, U.S. Dept. of Health & Human Services, Public Health Service, Alcohol Drug Abuse & Mental Health Admin., National Inst. of Mental Health, Laboratory of Psychology & Psychopathology, *Bethesda, Maryland* 20014 (Z01 MH 00476-08 LPP)

This study of children of schizophrenics is based on data from an NINCDS study of pregnancy and delivery conditions in a large group of women, which included psychological and neurological tests on the offspring, studied until age 8. We have found that: (1) There were more fetal deaths among the offspring of schizophrenics. (2) The IQ scores of the surviving offspring of schizophrenics appear to be more related to adverse perinatal factors than do IQ scores for the controls. (3) The behavior of the surviving male offspring of schizophrenics was more often rated as hyperactive or immature at age 7 than was the behavior of controls. These offspring also had more soft neurological signs, especially abnormal hand-arm coordination.

CHILDREN AND FAMILIES VULNERABLE TO MENTAL DISORDERS

L.C. Wynne, University of Rochester, School of Medicine & Dentistry, Dept. of Psychiatry, *601 Elmwood Ave., Rochester, New York* 14627 (P01 MH 22836-08)

The major overall objective of this program is to study families with children believed to have varying degrees of risk for later mental disorder as well as for intermediate outcomes (assessed in terms of degrees of competence versus psychiatric dysfunction). Risk for dysfunction in these children is based upon the diagnosis of a serious mental disorder that has required hospitalization in at least one parent; alternative risk indices based upon deviant family communication patterns also are being studied and can be compared with parental diagnosis as a risk variable. The vulnerability of the children was assessed during the initial evaluations with psychophysiologic measures, psychological tests, and clinical studies, both current and historical.

During the past year, 34 families participated (or are now involved in) our 3-year followup. This brings the total followup to 94 families as of 9/1/79. Five additional families who had move out of town were located and have agreed to participate in any feasible manner. Thus far 88 percent of the 113 families contacted have agreed to participate in the followup. During the coming year, analysis of data from the initial evaluation and the completion of followup data collection will occupy major attention in this program. Analysis and interpretation of data across substudies are now of special interest. For example, study of the relationship between diagnostic data about the parents will be compared with family interaction measures as predictors of school performance, child psychophysiologic indices, and psychological test measures of the children.

STUDY OF CHILDREN AND GRANDCHILDREN OF PATIENTS WITH DEPRESSIVE ILLNESS

L. Cytryn, U.S. Dept. of Health & Human Services, Public Health Service, Alcohol Drug Abuse & Mental Health Admin., National Inst. of Mental Health, Unit on Childhood Mental Illness, *Bethesda, Maryland* 20014 (Z01 MH 00098-05 BP)

It is the long range purpose of this project to determine the frequency of affective disorders in the children of adults with unipolar and bipolar depressive illness, and to identify biological makers of a genetically transmitted predisposition to affective disorders, and to study the interaction between genetic predisposition and environmental factors in children with affective disorders. Our present project is refined replication of our pilot project reported last year. The major changes involve the inclusion of two control groups as well as a blind interviewer and rater.

A BEHAVIOR PROFILE FOR CHILD PSYCHOPATHOLOGY AND SOCIAL COMPETENCE

T.M. Achenbach, U.S. Dept. of Health & Human Services, Public Health Service, Alcohol Drug Abuse & Mental Health Admin., National Inst. of Mental Health, Developmental Psychology Laboratory, *Bethesda, Maryland* 20014 (Z01 MH 00244-04 LDP)

The purpose of the research is to develop a standardized behavioral profile for child psychopathology and social competence to be used for research on etiology, treatment effects, epidemiology, and prognosis, as well as for clinical purposes. Parents of disturbed and normal children fill out a behavior checklist describing their child's behavior problems and strengths. Data from the checklists are factor analyzed to identify items that group together within various age and sex groups. The factors are employed as scales of the behavior profile. Empirically obtained distributions of scales on each score provide norms with which the scores of individual children can be compared, and behavior profiles obtained on the same child at different times can be used to assess changes in behavior.

BEHAVIORAL PROBLEMS AND COMPETENCIES OF CLINIC-REFERRED AND NONREFERRED CHILDREN

T.M. Achenbach, U.S. Dept. of Health & Human Services, Public Health Service, Alcohol Drug Abuse & Mental Health Admin., National Inst. of Mental Health, Developmental Psychology Laboratory, *Bethesda, Maryland* 20014 (Z01 MH 00263-03 LDP)

In order to compare the behavioral problems and competencies reported for clinic-referred and nonreferred (normal) children, a survey of 1300 randomly selected parents in the Washington, D.C. area was conducted. Home interviewers administered the Child Behavior Checklist to parents of 50 boys and 50 girls at each age 4 through 16. The results have been compared with parental reports of problems and competencies for clinically referred children matched to the nonreferred children for age, sex, socioeconomic status, and race in order to provide a unique epidemiological baseline for research on child psychopathology and the effectiveness of various treatments.

A STUDY OF AFFECTIVE DISORDERS AMONG OLD ORDER AMISH

J.A. Egeland, University of Miami, School of Medicine, Dept. of Psychiatry, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152 (R01 MH 28287-03S1)

The objectives are to clarify selected issues related to the causation and classification of affective disorders (manic-depressive illnesses). The primary focus is on the genetic basis for bipolar and unipolar forms of depressive illness. The research setting is the Old Order Amish community of Lancaster County, Pennsylvania. This is a homogeneous, endogamous (inbred) group, where total genealogical assessment is possible, making it uniquely suited for identification and control of genetic variables.

There is full ascertainment (period prevalence) of cases of mental disturbances for the three-year period, 1977-1979. A Board of five psychiatrists provides independent diagnoses of the clinical case materials, using the Research Diagnostic Criteria. Confirmed instances of primary affective disorders serve as probands for the bipolar and unipolar samples.

The present emphasis is on SADS-L interviewing of all first degree relatives of bipolar probands to develop extended pedigrees with multiple cases of illness. Several of these informative pedigrees will be selected for linkage analysis by studying blood types, color blindness and other known genetic loci.

SEX DIFFERENCES IN MORBIDITY AND HEALTH ACTIONS

L.M. Verbrugge, University of Michigan, Ann Arbor Campus, School of Public Health, Dept. of Biostatistics, *Ann Arbor, Michigan* 48104 (R01 MH 29478-03)

Health surveys repeatedly show that females have higher rates of illness, disability days, and health services use than males. Numerous hypotheses have been proposed to explain the sex differences. They involve health attitudes and beliefs, social roles, social stress. health reporting behavior, life style behaviors, and genetic factors. The purpose of this research is to determine how social and social psychological factors affects reports of symptoms, disability, and other curative health actions, and how these factors explain sex differentials. The basic research design is: A sample of white adults in the Detroit metropolitan area keep health diaries for six weeks. Each day, respondents record information about all symptoms experienced, the perceived severity of those symptoms, restricted activity due to symptoms, medical or dental attention (for symptoms or for preventive reasons), medicine use (for symptoms or preventive reasons), communications with peers and kin about symptoms, mood, and events of the day which were unusual. Two interviews occur--one before the diary period to measure the main predictors, and one at the end of the diary period for retrospective health information and for reactions to the diary task. The Daily Health Records provide the main dependent variables for analysis; the Initial Interview provides the main predictors. Some important innovations of the research are: the use of a health diary among males and persons of low socioeconomic status; self-response (no proxy reports allowed); reports of all symptoms experienced, not just those which prompt some curative action; daily entries in the diaries rather than entries only on symptomatic days; and extensive information on lay communications and medicine use.

THE EPIDEMIOLOGY OF DEPRESSION IN NORMAL CHILDREN

M.M. Lefkowitz, State Dept. of Mental Hygiene, *44 Holland Ave., Albany, New York* 12208 (R01 MH 29788-03)

The primary objective of this phase, II, of the proposed research is to determine the prevalence of symptoms of depression in a normal population of children. A secondary goal is to study certain hypothesized antecedents of childhood depression. Accomplishment of the first objective will be through the application, epidemiologically, of peer nomination inventory of depression to a representative sample of elementary school children. This technique was developed and standardized in Phase I of the research and was shown to be psychometrically sound. The second objective will be accomplished by means of individual, precoded, interviews with samples of mothers whose children were classified as depressed and nondepressed. Data will also be gathered from self-ratings and school records. For the epidemiological data, the prevalence of depression, identified by a cutoff score developed in Phase I, will be presented for various categories of children. The prevalence of separate symptoms of depression occurring in the normal and pathological ranges will also be presented. Analyses of the interview data will be by discriminant function and multiple regression.

MEASUREMENT PROBLEMS IN PSYCHIATRIC EPIDEMIOLOGY

R.E. Roberts, University of Texas, Health Science Center at Houston, School of Medicine, Dept. of Psychiatry, *Box 20036, Houston, Texas* 77025 (R01 MH 30118-02S1)

The objective of the research is to examine the role of response error (trait desirability, need for social approval, response acquiescence) in field studies of the prevalence of psychiatric impairment. Data will be acquired by household interview using a stratified sample (N equals 1,350) with optimal allocation by socioeconomic status and ethnicity. The sampling frame to be used is the almost 8,000 respondents interviewed in 1974 in Alameda County, California by the Human Population Laboratory for Epidemiologic Studies. Ethnicity is defined using ethnic heritage, e.g., Blacks, Mexican American, and Anglos. Response tendencies will be studied in relation to two psychiatric screening instruments: the Center for Epidemiologic Studies Depression Scale (CES-D) and the Psychiatric Epidemiology Research Interview (PERI). Data analysis will focus on the magnitude and direction of error introduced by response tendencies in contrasting sex, socioeconomic status, and ethnic groups. For example, how much variance in symptom scores are attributable to response tendencies as compared to sex, socioeconomic status, and ethnicity. A second focus is on the effects of response bias on the sensitivity/specificity of the CES-D and the PERI in contrasting ethnic, sex, age, and income groups. One-two weeks after being interviewed initially by lay interviewers, respondents will be re-interviewed by clinical psychologists using the Schedule for Affective Disorders and Schizophrenia.

2.0240,

STRESSFUL LIFE EVENTS, SOCIAL SUPPORT AND ILLNESS

A. Dean, Union University, Albany Medical College, School of Medicine, Dept. of Psychiatry, *47 New Scotland Ave., Albany, New York* 12208 (R01 MH 30301-03)

The causal relations among stressors, social support and illness will be examined in a longitudinal study. The primary purpose is to ascertain the intervening effect of social support between stressors (stressful life events) and illness (both physical and psychiatric disturbances). However, the design will allow us to examine the alternative models in which the stressors may serve as intervening variables or the illness may play a primary causal role in the occurrences of stressors and the erosion of social support.

In our current project, a representative sample (N equals 1100) of adults from a tri-city area (Albany-Schenectady-Troy, which is also a Census SMSA area) were studied in order to construct reliable and valid measures of social support and to test a number of hypotheses regarding the relationships among stressors, social support and illness. The cross-sectional data yielded a number of reliable and valid scales of social support (e.g., instrumental support, expressive support, durability of a confidant and neighborhood and community satisfaction) and showed that these scales contributed significantly to the variation of psychiatric (especially depression) symptoms (as measured by the CES-D and Gurin scales). These relations held, even when sociodemographic and stressors were taken into account. The proposed study will conduct two follow-ups on the same respondents. The three-wave design provides a most rigorous analysis of the causal patterns among stressors, social support and illness. Also included in the design will be measures of history of illness, health help-seeking behavior, and a psychological factor (locus of control).

For analyses, the generalized least squares with instrumental variables approach (GLS-IV) and the structural equation modelling approach will be utilized.

WHO-NIMH STUDY OF DETERMINANTS OF MENTAL DISORDERS

L.C. Wynne, University of Rochester, School of Medicine & Dentistry, Dept. of Psychiatry, *601 Elmwood Ave., Rochester, New York* 14627 (R12 MH 30322-03)

WHO and NIMH are conducting a collaborative cross-cultural study of psychosocial determinants influencing course and outcome of severe mental disorders, especially schizophrenia. This program is a replication and successor to the International Pilot Study of Schizophrenia (IPSS). This application for a Supplement grant application is intended to make possible continuity of data collection for the period from January to June, 1980, midway in a two-year study of administrative incidence of schizophrenia in a defined catchment area.

Comparative studies in Rochester and Hawaii are being conducted to carry out the U.S. role in the WHO program. The Rochester Field Research Center is participating in the modification and development of a series of instruments for diagnosis, study of life events, and the study of familial prognostic indicators. Computerized linkage between the Psychiatric Register and the Cancer Register is in progress. Comprehensive epidemiologic study of the administrative incidence of essentially all cases of schizophrenia of less than three months' duration is taking place, with the application of all of the various research instruments for the prediction and assessment of course and outcome. The methods for assessing the families of these patients include the Camberwe Family Interview for studying 'Expressed Emotion' and several alternative shorter methods for assessing family communication, emotional interaction, and perceptions of illness. Ethnographic comparisons are also a component of this collaborative program.

PRENATAL EXPOSURE TO HORMONES IN MAN AND ANIMAL

J.M. Reinisch, Rutgers the State University of New Jersey, New Brunswick Campus, School of Arts & Sciences, Dept. of Psychology, *Old Queens Bldg., New Brunswick, New Jersey* 08903 (R01 MH 30676-03)

The overall objective of this research is to identify the long term effects resulting from prenatal exposure to steroidal hormones in humans. The foci of these studies are the synthetic estrogen diethylstilbestrol (DES), which has been related to a rare form of vaginal cancer in young women and girls as well as genital abnormalities in male offspring; and the synthetic progestin 19-nor 17-alpha-ethinyltestosterone (19NET), the most androgenic and potent of the synthetic progestins causing masculinization of the external genitalia in approximately 18 percent of exposed female offspring. An attempt is being made to identify and elucidate the sequelae of exposure to DES and 19NET on the offspring of mothers administered these preparations during pregnancy. Evaluation is designed to test the possible effects on cognitive abilities, personality/temperament, brain lateralization, motor performance, and IQ in comparison to unexposed siblings. Parallel studies employing stringent experimental procedure and comparative methodology with mice, in which the control of dosage and timing schedules as well as the random assignment of subjects to groups is possible, are designed to produce precise deliniation of the effects of DES and 19NET on behavior and aspects of physiology. Further, the study of the laboratory animal permits the administration of hormone regimes which closely approximate those given humans, thereby enabling results from these experiments to be used both to generate suggestions for new avenues of inquiry in the research with humans as well as to assist in the interpretation of the data generated from the human subjects.

PHYSICAL VIOLENCE IN AMERICAN FAMILIES

M.A. Straus, University System of New Hampshire, University of New Hampshire, School of Liberal Arts, Dept. of Sociology, *Durham, New Hampshire* 03824 (R01 MH 27557-04)

Continued analysis of data on a nationally representative sample of 2,143 families is proposed. Work to date has provided the most accurate (and in some cases the only) incidence rate statistics on physical violence between family members, including, child-abuse, wife-beating, husband-beating, violence by children toward each other, and violence by children towards parents. Further analysis is needed because the work to date has been largely descriptive analyses of incidence data and analysis of two-variable relationships, and because a number of important issues are still to be investigated. Eleven needed analyses are described. Examples of the questions which these are designed to answer are: (I) What is the relationship between the balance of power between husband and wife and the use of physical violence? How is this affected by such factors as the social class of the couple, and the degree to which the wife is economically independent of the husband? (2) What accounts for group differences in rates of family violence? Among the group differences to be studied (because work to date shows important differences) are the region of the country, socioeconomic status, and race. (3) Is involvement in a primary group community of friends and kin associated with a lower level of family violence, and why? (4) We have found a strong relationship between growing up in a violent family and being violent to one's spouse and children. What about those who do not follow this pattern? Do they have family patterns which will suggest ways to break the generation to generation cycle of violence? The importance of finding answers to questions such as these stems from the extremely high violence rates demonstrated by this project. This adversely affects the quality of family life and is part of the explanation to the high level of violence in the society. There is clearly a need for continued research which can suggest policies to reduce family violence.

LONG-TERM EPIDEMIOLOGICAL STUDY OF BEHAVIOR DISORDERS

H.R. Huessy, University of Vermont & State Agricultural College, School of Medicine, Dept. of Psychiatry, *85 S. Prospect St., Burlington, Vermont* 05401 (R01 MH 27881-04)

The current literature implies that childhood symptoms of hyperkinesis (or minimal brain dysfunction) are predictive of adult maladjustment. Most of the follow-up research in this area has been conducted on specialty clinic populations, located mostly in urban centers. This has produced a skewed sample with regard to most behavioral and clinical measures. Since 1966 we have followed 501 children then in the second grade representing all of the second grade children in a collection of rural and suburban schools. Signs of hyperkinesis in the early years reliably identified a population at risk for maladjustment, both social and academic, in the ninth grade and recently again in the twelfth. More extensive analyses have confirmed and amplified these results.

We now propose to conduct extensive personal interviews with each subject in our study. The interviews would cover the social, occupational, legal and psychiatric status of our subjects. We then plan to relate the interview data to performance in second, fourth, and fifth grade. These results will enable us to trace the course of the hyperkinetic syndrome and to suggest ways of identifying subjects at risk early in life, thus permitting therapeutic intervention before problems become acute.

MENTAL HEALTH OF THE POOR BLACK ELDERLY

A.O. Faulkner, Rutgers the State University of New Jersey, New Brunswick Campus, Graduate School of Social Work, *Old Queens Bldg., New Brunswick, New Jersey* 08903 (R01 MH 27894-02)

The purpose of this study is to identify factors associated with maintenance and change of mental health in poor, urban black elderly using a longitudinal approach.

A panel of 150 black men and women over 60 years of age are being contacted at short, regular intervals for repeated psychological, social, and physiological measurements, including a yearly medical check-up, for a period of three years. The project is being carried out in Newark, New Jersey. The longitudinal nature of the project is optimized by including in the sample surviving members of a study on the mental health of the black aged by the same investigators. Personal and social data on this group are available for 1972 and 1974, and many of the measurements are being repeated in the current research.

Eighty two persons from the previous panel are participating in the longitudinal study and data have been obtained on changes in health and health care needs, housing and income, relations with family and friends and general outlook on life since they were last seen in 1974. Information has also been collected on the deceased members of the panel, including living conditions prior to death, situation surrounding death, cause and place of death. Correlates of mortality and survivorship are being investigated.

A new sample has been drawn from the same area to bring the current panel to 150 persons. Variables considered include physical and mental health, life styles, self-concept, life satisfaction and morale, depression, social interaction and isolation, use of available services, environmental conditions, family and friendship networks, need and use of short term and long term care facilities. Analysis of the data will pay particular attention to changes that occur with time.

EPIDEMIOLOGIC STUDY OF BEHAVIOR PROBLEMS IN CHILDREN

F.J. Earls, Harvard University, Boston Campus, Childrens Hospital Medical Center, Dept. of Psychiatry, *300 Longwood Ave., Boston, Massachusetts* 02215 (R01 MH 28266-03)

This proposal represents the continuation of a series of epidemiologic studies on the natural history of behavior problems in preschool children living as permanent residents on Martha's Vineyard Island, seven miles off the coast of Massachusetts. Two studies are proposed. The first is an etiologically oriented investigation into the determinants of behavior problems in three year old children. Stressful life events in parents and in the children themselves, and temperamental characteristics of children are the two principal groups of variables hypothesized to determine the presence of behavior problems. An interview method developed by Brown is used to measure the impact of life events, and parent questionnaires designed by Carey are used to examine the temperaments of children. The dependent variable, behavior problems, is determined from a parent interview, the Behavior Screening Questionnaire of Richman and Graham, and from direct observation of the children in a play paradigm.

The sample for this study is the total population of children, aged 0-3 years, arranged in sequential age cohorts. Parents are interviewed once a year up to and including the child's third birthday to collect data on the independent variables. Parents and the children are separately interviewed near the child's third birthday to determine the behavior adjustment of the children.

The second study is a 4 year follow-up of children seen as part of the preliminary, prevalence study in 1978. One hundred families will be recontacted to conduct parent and child interviews. In addition, school reports will be obtained. The methods for this study are adopted from the Isle of Wight project reported by Rutter, et. al.. Data from this work will be linked with data from the prevalence study to determine the incidence and duration of behavior problems in young children, and the predictive validity of the behavior assessment methods used in that study. The significance of these studies relates to the primary and secondary prevention of psychiatric disorder in children.

GENETIC STUDIES OF DEPRESSIVE DISORDERS

M.M. Weissman, Yale University, School of Medicine, Dept. of Psychiatry, *333 Cedar St., New Haven, Connecticut* 06510 (R01 MH 28274-04)

Using epidemiologic techniques, we will: 1. investigate the role of genetic factors and modes of genetic transmission in subtypes of depressive disorders by segregation and linkage studies of pedigrees; 2. develop more precise genetic models and apply these new as well as existing models to the data; 3. develop more precise clinical definitions of the familial manifestations of mood disorders; 4. explore the relationship between a variety of social and clinical characteristics of probands and morbid risk of psychiatric disorder in their relatives.

The probands will be selected from four distinct populations and will include a broad spectrum of affective illness (bipolar, severe unipolar, less severe unipolar depressives) and a matched nonpsychiatric normal control group. Approximately four first-degree relatives and a spouse will be interviewed per proband, including the relatives of the normals. Additional information will be collected by family history. Information for determining the diagnosis of relatives and probands will be obtained by detailed structured interview (Schedule for Affective Disorders and Schizophrenia) and will be applied to precise diagnostic criteria (Research Diagnostic Criteria). Identical methodology and diagnostic criteria will be applied to all probands, relatives, and population subjects. About 60% of the interviews have been completed. Reliability between raters and validity of the instruments have been established, and many computer programs required for data analysis have been completed.

SOCIAL STRESS, SOCIAL SELECTION & PSYCHIATRIC DISORDERS

B.P. Dohrenwend, Columbia University, College of Physicians & Surgeons, Dept. of Psychiatry, *630 W. 168th St., New York, New York* 10032 (R01 MH 30710-02)

One of the most persistent issues in psychiatric epidemiology centers on social class: Are rates of some types of psychiatric disorder higher in lower social classes because of greater social stress; or are rates higher because genetically predisposed persons are selected into or fail to rise out of lower class environments? The long term goal of the present research is to use a quasi-experimental strategy to test these contrasting social stress-social selection explanations. The strategy involves comparisons of advantaged and disadvantaged ethnic groups with social class controlled, and tests of related predictions concerning group differences in the types and magnitudes of stressful life events experienced. The present study is pilot study designed to determine the feasibility of implementing the quasi-experiment in Israel.

There are two main reasons for this choice of research setting: First, the quasi-experimental strategy requires an open society in which ethnic assimilation is taking place. Second, study of the processes involved and their consequences can best be accomplished when a well kept Population Register and Psychiatric Register are available. Israel, probably uniquely, meets both sets of requirements.

The long term goal is to compare relatively disadvantaged African and Asian Jews with relatively advantaged Jews of European origin in investigations of large samples of adult subjects. Comparisons would be made of true rates of schizophrenia, affective psychosis, antisocial personality, alcoholism or drug addiction, and neurosis, as well as for certain types of empirically derived symptom clusters. The measuring instruments would consist of the Psychiatric Epidemiology Research Interview (PERI) and Spitzer et al.'s SADS. The purpose of the present two year pilot study is to translate, test and calibrate these instruments which were developed in the United States in the different sociocultural setting of Israel. These tests are being conducted in interviews with 200 subjects sampled from different ethnic groups in Jerusalem and 240 psychiatric patients from the same ethnic groups.

PREPUBERTAL DEPRESSION - PHARMACOLOGY AND GENETICS

J. Puig Antich, New York State Psychiatric Inst., Dept. of Child Psychiatry, *722 W. 168th St., New York, New York* 10032 (R01 MH 30838-03)

In our pilot work we have shown that a group of children fitting RDC criteria for major depressive disorder in adults, can be identified by structured interview. We propose to study in these children psychobiological parameters which are known to be relevant to adult depressive illnesses. This will be done in order to: 1) Validate the diagnosis of prepubertal depressive illness and 2) Establish its relationship to adult depressive illnesses. In order to meet this objective we will carry out three interrelated studies: Study I is a double blind placebo controlled study of imipramine, coupled with studies of drug bioavailability. Study II is a genetic family study, comparing the prevalence of affective disorder and alcoholism in families of probands and controls. Study III is a long-term follow up of index children and controls.

In an interlocking application being submitted simultaneously three other parameters are to be studied: sleep, endocrine and MHPG excretion.

MEDICAL CONTEXTS AND SEQUELAE OF DOMESTIC VIOLENCE

W.H. Frazier, Yale University, School of Medicine, Dept. of Surgery, *333 Cedar St., New Haven, Connecticut* 06510 (R01 MH 30868-02)

The methodology of complete case review of medical records has been tested in a pilot study of domestic assaults upon women. This study points toward a 'battered woman syndrome' which may be as distinct and identifiable as the 'battered child syndrome'. The results indicate inter-relations between battering and subsequent child abuse, suicide attempts, physical disease and mental illness.

In the present study, the medical records of a sample of women treated for injuries in the emergency room, mothers of battered children, and women who attempt suicide will be abstracted and computerized.

The objective of this research is to refine case-identification techniques, to further characterize the population of battered women by describing the prevalence, clinical symptomatology and physical and mental health contexts and sequelae of battering and to specifically investigate battering among two high risk groups isolated in the pilot study: mothers of battered children and women who attempt suicide. The computerized medical record abstraction will also be used to identify present patterns of the medical treatment of battered women and to estimate the effect of intervention upon the course of the battering syndrome.

NIMH COLLABORATIVE PSYCHOBIOLOGY DEPRESSION PROGRAM

M.B. Keller, Massachusetts General Hospital, Psychiatry Service, *32 Fruit St., Boston, Massachusetts* 02114 (R12 MH 25478-06)

The overall purpose of the NIMH-CRB Program is to investigate clinical, genetic, biological and psychosocial aspects of the nature and etiology of depression and the affective disorders. The proposed investigation will employ clinical psychopathological and genetic-familial methods in a sample of over 1000 patients overall in the collaborative projects.

The grant proposes two major sets of studies, clinical psychopathology and genetic and family studies. The basic hypotheses common to these studies is that the affective disorders are heterogeneous as regards etiology, clinical features and response to treatment. Precisely defined homogeneous nosological classes validated by multiple external correlates will facilitate identification of risk factors for epidemiological studies and verification of hypotheses as to etiology and pathogenesis.

Goals set for this current year of the study include hiring and training of personnel, inclusion of subjects into the study, 6-month, 12-month, 18-month and 24-month follow-up evaluations of patients already included, continued co-ordination of the follow-up phase for the entire study, and preliminary analyses of the 6-month and 12-month follow-up data.

PROFILE - BLACK MALES AT RISK TO LOW LIFE EXPECTANCY

R.E. Dennis, Meharry Medical College, School of Medicine, Dept. of Psychiatry, *1005 18th Ave. N., Nashville, Tennessee* 37208 (R01 MH 26702-04)

Vital statistics list homicide as the leading or second most frequent cause of death for black American males between the ages of 15 and 29. The homicide rate is ten times higher for black than white men, and has contributed to a decline in the life expectancy of black men between 1960 and 1970. Yet little is known about these men who die of homicide, for vital statistics records only such limited information as age, occupation, and marital status of the deceased.

The long term goal of ths research project is to contribute to the literature on black homicide and to encourage consideration by policy makers as to how to increase the life expectancy and quality of life of black men in the United States.

The present research, originally funded for two years beginning June 1, 1976, is intended to provide a profile of black men at risk of dying young. The men are located in Nashville, Tennessee, and range in age from 18 to 35. The study groups were selected on the theory that homicide victims and perpetrators are not greatly dissimilar (hence 150 convicted felons of homicide are included), and on the theory that, had circumstances been slightly different, assault victims who survive might indeed have died (hence 150 assault victims). A third comparison group of 200 subjects is being selected from a random sample of households. These 500 men are being administered questionnaires inquiring into their social origins and institutional contexts, and three psychological tests from which ratings are being derived.

Central to the research is collaboration with a panel of local policy makers and behavioralists who will review findings of the research and guide the development of the intervention and policy proposals which emerge from the profile.

The original grant underestimated the tremendous effort and resources required to locate and interview the designated research subjects and as a consequence data collection is behind schedule. Two years of additional funding are requested to make possible the preparation and analysis of these data, and the write-up of the profile and policy recommendations.

SHETLAND - THE EFFECTS OF RAPID CHANGE ON MENTAL HEALTH

D.H. Rosen, University of California, San Francisco Campus, School of Medicine, Dept. of Psychiatry, *551 Parnassus Ave., San Francisco, California* 94122 (R01 MH 26997-05)

It is rare that one can study the effect which rapid industrial development will have on a rural, homogeneous, and isolated population. Such an opportunity is now present in the Shetland Isles. Large quantities of oil were discovered in the North Sea and starting in 1978, oil will be piped to Shetland for stoage, processing, and transport. This industrial development probably will bring about significant social change on islands where the people have lived simply and peacefully for centuries. Since major oil developments were not underway until 1976, Shetland lended itself well to a planned study of a prospective and longitudinal nature and in 1975, we initiated the baseline phase of just such a long-term research project.

It is our hypothesis that the industrialization and subsequent rapid social change will have a deleterious effect on the islanders' way of life (social organization) and their health (and mental health).

This present three year renewal grant proposal is a request for funds that will allow us to test our hypothesis and complete the analysis, interpretation and reporting to data comparing baseline and three year follow-up data.

CLINICAL RESEARCH CENTER STUDY OF AFFECTIVE DISORDERS

D.J. Kupfer, University of Pittsburgh, School of Medicine, Dept. of Psychiatry, *3550 Terrace St., Pittsburgh, Pennsylvania* 15261 (P50 MH 30915-03)

Depression is the most common disabling psychiatric illness and the source of enormous human suffering. Depressive symptoms can be identified in over half of all patients seen in psychiatric practice and it is well known that only a small proportion of those suffering milder forms of depression ever seek medical attention. That depressive features are almost inevitably present in the wake of adverse life situations is accepted as part of the human condition. Depressive symptoms, however, also occur in association with chronic illnesses or as sequelae of both acute and chronic illnesses and injuries, and are often observed in individuals who abuse alcohol, other central nervous system depressants, or narcotics. The Department of Psychiatry (WPIC) of the University of Pittsburgh Medical School in collaboration with the Department of Psychology has proposed the establishment of a MHCRC to investigate the etiology, epidemiology, and treatment of affective disorders. The proposed MHCRC would provide the essential structure and fiscal support to realize the potential for an integrated, multidisciplinary program of investigation, research training, and clinical service. The proposed research program is organized around four major themes: life-span studies of the phenomena of depression (children to the elderly), social and psychological factors in depression, biologic factors in the etiology of depression, and prevention and maintenance treatment studies in affective illness. It should be emphasized, however, that each of the specific proposed investigations is likely to cut across several areas, and thus will provide some of the basis for the communication and collaboration which is fundamental to the MHCRC's goal. Twenty-five specific projects designed to study various facets of depressive illness are detailed in the proposal. All of these projects are either underway or in the preliminary stages of pilot investigation. In addition, a series of new programs of investigation is outlined (including studies in assessment, epidemiology, genetics, clinical psychopharmacology, neurochemistry, psychosocial factors, and neuroendocrinology) which would be developed under the aegis of the proposed MHCRC.

CLINICAL RESEARCH CENTER FOR STUDY OF MAJOR PSYCHOSES

H.Y. Meltzer, University of Chicago, School of Medicine, Dept. of Psychiatry, *5801 S. Ellis Ave., Chicago, Illinois* 60637 (P50 MH 30938-02)

A multidisciplinary study of the major psychoses was initiated in Nov. 1977. Approximately 100 psychotic patients are evaluated each year with the Present State Examination, a detailed psychiatric history and family history schedule, and longitudinal assessment of clinical change using instruments such as the Schedule for Affective Disorders Change scale. The patients are also studied with a variety of biochemical, neuroendocrine and neurophysiological measures. At intervals of at least one year, follow-up interviews will be collected. Specific research projects include: 1) comparison of various criteria for the diagnosis of schizophrenia; 2) stability of acute symptoms upon readmission; 3) comparison of symptoms, history, response to lithium of patients with schizoaffective illness, affective illness and schizophrenia; 4) H-reflex recovery curve as a function of psychiatric diagnosis; 5) prolactin and growth hormone response to apomorphine; 6) neuroleptic blood levels as a predictor of clinical response and correlate of serum

prolactin levels; 7) platelet and plasma monoamine oxidase activity in schizophrenia; 8) dose-response curves for effects of neuroleptics on serum prolactin levels and H-reflex in schizophrenics and controls; 9) serum DBH activity in psychotic depression; 10) effect of tricyclic anti-depressants on rat plasma prolactin levels following low dose or high dose 5-hydroxytryptamine; 11) super-sensitivity to serotonin agonists induced by para-dilorophenylalanime; 12) ability of dopamine agonists to decrease rat plasma prolactin levels; 13) effect of alpha-methyl-paratyrosine and monoamine oxidase inhibitors on serum prolactin levels in man.

EPIDEMIOLOGY OF RECENTLY BEREAVED WOMEN

G.W. Comstock, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 MH 31257-02)

This study has two major purposes: (1) to see if there are adverse physical and mental health effects associated with bereavement of sexagenarians; and (2) to identify factors associated with amelioration or aggravation of these health effects.

A prospective epidemiologic study is proposed of women 65 to 70 years of age; a group at high risk of becoming widowed. They will be interviewed before this event takes place and will be followed for two years after the death of the spouse. The major focus will be to study the health effects of this event, both physical and psychiatric and the factors that may mediate between the event and the effects. Data will be gathered from all of the women in this age group who are still married at the time of interview. Questions will concern health, social support systems, functioning, life satisfaction, and depression. As each woman becomes widowed, she will be matched to three non-widowed women, and they will be followed for a two year period. Each one will be interviewed five times (every 6 months) in addition to the baseline interview. Comparison will be made between the widowed and non-widowed and differences among the widow will be examined.

EPIDEMIOLOGICAL GENETICS AND FAMILY STUDY

T. Reich, Washington University, School of Medicine, Dept. of Psychiatry, *660 S. Euclid Ave., St. Louis, Missouri* 63110 (P50 MH 31302-02)

The major psychiatric disorders are both common and familial. Affected individuals tend to have immediate relatives who suffer the same type of disorder and many generations of a kindred may contain affected individuals. For some illnesses such as schizophrenia and the major affective disorders, there is evidence that both genes and environment are important. Our Center includes theoretical and clinical approaches to understanding this important phenomenon. New methods are being developed for the measurement of early environmental factors and the way in which genetic and environmental factors interact to produce disorders is also being studied. Projects which improve methods for the assessment of early family environment; a study of the genetics of pre-senile and senile Alzheimer's dementia; and several theoretical projects whose goal is the development of new statistical approaches to gene-environment interactions are included. In addition there is a core of essential personnel who offer guidance to other Center members. New Projects are being developed and will be submitted for approval.

An important Center activity is the participation of many professionals from diverse disciplines in an educational and training program. The result has been an exciting, intellectual environment and the creation of new approaches to an age old problem.

PSYCHOLOGICAL DISTRESS AND HELP-SEEKING BEHAVIOR

E. Berkanovic, University of California, Los Angeles Campus, School of Public Health, Dept. of Behavioral Sciences & Health Education, *405 Hilgard Ave., Los Angeles, California* 90024 (R01 MH 32459-01)

The purpose of this research is to analyze data that have already been collected on the experience of psychological distress, recognition of the need for help with emotional problems and help-seeking for emotional problems. These data will be linked to other data on the same respondents that were collected prior to the data on psychological distress. Sociodemographics, sociomedical indicators, and data on social supports and health orientations are included in the earlier data set. Taken together, these data sets permit two types of analyses. First, descriptive analyses of the distributions of psychological distress, recognition of need for help with emotional problems will be undertaken. Secondly, predictive analyses of the determinants of the recognition of need for help with emotional problems and help-seeking will be conducted.

ANOREXIA NERVOSA - PREVALENCE, DETERMINANTS, TREATMENT

P.E. Garfinkel, Clarke Inst. of Psychiatry, *250 College St., Toronto, Ontario, Canada* Zone 2B (R01 MH 32659-01)

The prevalence of anorexia nervosa will be determined by using height and weight data and scores on an eating attitudes test (EAT) from a sample of 8,000 students. Individuals whose data suggests eating disorder will be clinically interviewed to confirm the diagnosis. Similar data will be obtained from all students attending ballet schools (N equals 400) in order to determine whether anorexia nervosa is increased in adolescents who must focus increased concern on body size.

Patients with anorexia nervosa have previously been shown to display disturbances in body image and interoception. At present, little is known about the development and long term stability of these disturbances. Subjects with anorexia nervosa, obesity and controls will undergo perceptual testing weekly for 4 weeks. Personality, eating habits, weight and menstrual function will be assessed through the study period in order to more fully understand the perceptual disturbances.

While much speculation has focused on the role of the family in the development of anorexia nervosa, there has been no systematic study of this area. Parents of anorexic patients and controls will be studied in terms of their body perceptions, personality, attitudes to eating and weight and their interrelationships on the course of the disorder.

There is agreement that weight restoration is an important aspect of the treatment of anorexia nervosa. However, after weight is regained the role of further therapies is not known. After impatient weight restoration, anorexic patients (N equals 60) will be randomly assigned to different treatment groups (family therapy, individual supportive psychotherapy or referral back to family doctor). Measures of clinical change in the patient, her family and perceptions will be taken yearly for 3 years.

TYPOLOGY OF VIOLENT DEATH

F. Loya, University of California, Los Angeles Campus, Neuropsychiatric Inst., Dept. of Psychiatry, *760 Westwood Plaza, Los Angeles, California* 90024 (R01 MH 32699-01)

The goal of the proposed study is to develop a typological description of individuals who die violent deaths: accident, suicide and homicide. The typological description will be based upon the premise that violent death occurs as a result of a complex interaction among a) environmental influences, b) personal characteristics and c) the occurance of stressful life events. As such, violent death is conceptualized as a multidimensional, multidetermined phenomenon.

Traditionally, past research has focused on the study of a single mode of violent death, as if each mode were unrelated to others. Another problem has been the choice of populations to study. Despite the fact the minority group persons are known to be disproportionately involved in violent death, little scientific knowledge exists concerning the interaction between racial and ethnic group status and violent death. The proposed study will address these two deficits, particularly the racial and ethnic group dimensions, by focusing on a representative sample of all persons who die violent deaths during a three year study period in three urban cities. Of particular interest is the Spanish-heritage population as it is dispersed throughout the Southwest United States. Thus, collection of data will occur in Los Angeles, Denver, and Albuquerque on the basis of a) environmental data based on 974 census tract areas in these three cities, b) individual subject-victim data based on a 'dimensions' evolved from a) above and c) stressful life event data and other psychological data forthcoming from interviews with significant others. Cluster analysis will be employed to develop a social area analysis of the three cities and person cluster analysis will result in a typology of victims of violent death. These person-types, or groupings of persons based on their relation to census tract variables, will be the basis of other comparative analyses. The potential importance of the proposed work is chiefly in its promise of providing a valuable description of violent death, not only to enhance our basic understanding of these phenomena but such a typology also would aid in locating and identifying prevention services.

EPIDEMIOLOGY OF DEPRESSION IN TWO URBAN POPULATIONS

B.J. Gurland, Columbia University, College of Physicians & Surgeons, Dept. of Psychiatry, *630 W. 168th St., New York, New York* 10032 (R01 MH 32794-01)

Proposed is collaborative secondary analysis of data banks acquired in large scale psychiatric epidemiological investigations of two samples of the New York City population: 1. The twenty-year follow-up of the Midtown Manhattan Study panel (N equals 695) interviewed in 1954, at age 20-59 and again in 1974, at age 40-79. 2. The cross-sectional study of a city-wide geriatric sample (N equals 447), age 65 plus, conducted in 1975 by the Department of Geriatric Research (DGR) in the New York State Psychiatric Institute.

Primary focus will be on comparisons of the 'old old' (72-79), the new elderly (65-71), with their juniors in the Midtown Longitudinal Study (MLS) panel, their seven kinds of morbidity outcomes, including depressive manifestations, present at 1974 follow-up. A large series of their potential social and existential predictors (antecedents) of morbidity identified at four different stages of the life history from the pre-adult onward will be statistically evaluated, using a number of multivariate methods.

Points in the DGR sample of substantive and methodological congruence with those of the geriatric segment of the MLS panel will be analyzed for (1) similarities and differences that may enlarge epidemiological knowledge, (2) relevance for collaborative designing, instrumentation and implementation of a terminal follow-up of the Midtown panel in 1984.

The analyses will also be targetted toward estimating future service needs in the urban geriatric population, and toward providing guidelines for planning preventive measures to reduce the high rates of a series of geriatric morbidities.

VULNERABILITY FOR DEPRESSION

P.M. Lewinsohn, Oregon State Higher Education System, University of Oregon, School of Liberal Arts, Dept. of Psychology, *1472 Kincaid St., Eugene, Oregon* 97401 (R03 MH 32805-01)

The purpose of this proposal is to complete data collection and data analysis for an epidemiological pilot study on a community sample of approximately 1500 persons. The basic goal is to test hypotheses about the antecedents for depression, i.e. to identify factors which characterize people who are likely to become depressed in the future. Most of the Ss have already been assessed on a wide range of measures. They will be followed for one year during which time their depression level will be monitored on a monthly basis. Clinical assessments will be done on subjects who become depressed during the course of the study. Comparisons will be made between the latter and a control group of Ss who do not become depressed. Groups will be further divided into those who do and those who do not have a previous history of depression. While the data will be used to test substantive hypotheses, the major goal is to test the over-all methodology prior to launching a larger longitudinal, prospective epidemiological study of depression.

HOME SLEEP DIAGNOSIS FOR THE AGED

D.F. Kripke, University of California, San Diego Campus, School of Medicine, Dept. of Psychiatry, *P.O. Box 109, La Jolla, California* 92093 (R01 MH 33282-01)

Epidemiological data suggest that, especially among the aged, sleep complaints predict several percent of all deaths. Use of sleeping pills is associated with further increases in mortality. Nevertheless, we do not know the prevalence of objective sleep disorders among the elderly, the causal mechanisms of sleep disorders in mortality, or the balance of benefits and risks in long-term use of prescription hypnotics. We lack this crucial knowledge although 10-30% of our population complains of insomnia or uses prescription hypnotics. It has been difficult to study sleep problems scientifically due to a lack of convenient, inexpensive recording metnods. This study will pioneer and evaluate a home and ambulatory diagnostic approach for sleep disorders among the elderly. Further, we will estimate the nature and prevalence of sleep disorders among the elderly in the San Diego Community. With the validation of home recording methods, the cost of scientifically diagnosing sleep disorders can be reduced by about 90%. Three home sleep recordings and one laboratory sleep polysomnogram will be made on each of 240 elderly volunteers. Reliability of measurement of sleep time and reliability of diagnosis will be evaluated between home and laboratory recordings and between sequential home recordings. Home recording techniques will be applied in future experiments to determine the true prevalence of sleep disorders, their role in population mortality, and the benefits and risks of hypnotic drugs.

LOCAL ECONOMY, STRESS AND MENTAL HEALTH

E.D. Sclar, Columbia University, School of Architecture & Planning, Dept. of Urban Planning, *Broadway & W. 116th St., New York, New York* 10027 (R01 MH 32871-02)

The purpose of this project is to investigate the relationship between changes in the structure of the economy of a local community and the impact which that has on the utilization of mental health services. The present project carries out its task by building statistical models to investigate the relationships extant in a very extensive data set containing information on a wide array of mental health service users in Fitchburg, Massachusetts, and in depth information on the changing structure of the local economy. The data set used extends back over a period of 27 years and contains information gathered monthly. In addition to exploring the primary relationship between economic change and mental health service utilization, the project looks at the secondary but equally important matter of the ways in which the mental health service system itself reacts to changing utilization patterns. This is accomplished by the use of data on the number and discipline of mental health professionals working at the local mental health center. This data too is gathered on a monthly basis.

EPIDEMIOLOGY OF DEPRESSION AMONG AMERICAN INDIANS

J.H. Shore, Oregon State Higher Education System, University of Oregon Health Sciences Center, School of Medicine, Dept. of Psychiatry, *3181 S.W. Sam Jackson Park Rd., Portland, Oregon* 97201 (R01 MH 33280-01)

This project is a proposal to study the epidemiology of the spectrum of depressive reactions in American Indian cultures. Since there is substantial evidence that cultural differences among American Indian tribes significantly effect behavior patterns and depressive reactions, this study is designed to compare the epidemiology of depression in a major southwestern tribe, the Papago, and a tribe of the northern plains, the Oglala Sioux. The research will be sponsored by the Department of Psychiatry at the University of Oregon Health Sciences Center in affiliation with the White Cloud Center for Mental Health Research and Development for American Indians. Selected staff members of the White Cloud Center, who have developed active collaboration with the Indian communities, will become project staff through the affiliation between the White Cloud Center and the UOHSC.

The research proposal involves utilization of the Psychiatric Epidemiology Research Interview (PERI). This instrument will be pretested in the Indian communities with a lexicon development of the individual subscales. After cultural sensitization of the PERI, research application will be made to five index and one community subject group. The five index groups include patients from the medical clinic, mental health clinic, law enforcement probation service, alcohol treatment program, traditional Indian medicine men. Special consideration will be given to prevent an overprediction of psychiatric illness from high subscale scores that reflect psychophysiologic distress to physical illness.

The data analysis will provide a description of the epidemiology of the spectrum of depressive reactions in these American Indian cultures with consideration for depressive responses in physical illness, stress reactions, primary psychiatric illness, antisocial behaviors, substance abuse, and special cultural syndromes.

EPIDEMIOLOGY OF PSYCHIATRIC NEED AND PRIMARY CARE

D. Mechanic, Rutgers the State University of New Jersey, New Brunswick Campus, Graduate School of Social Work, *Old Queens Bldg., New Brunswick, New Jersey* 08903 (R01 MH 33940-01)

This project examines the effects of psychological disorder and social need on patterns of medical care utilization, physician disposition of patient problems, treatments provided, and processes of referral to psychiatric services. Three samples were surveyed in a population area that was substantially rural but served by a single large multispecialty group practice: a sample of 1026 persons representative of the community population, 114 patients in this population seeking psychiatric care, and 316 Medicaid recipients residing in the same geographic area. Data from patient interviews have been merged with information from medical and pharmaceutical records for the 12-month period following interview. Psychological disorder, social need, sociodemographic characteristics, and group structure variables are used as predictors of patterns of utilization of medical and psychiatric services, disposition and referral by primary care practitioners to specialized psychiatric services, prescription of psychoactive drugs by primary care physicians and psychiatrists, and use of nonprescription drugs. Patterns are examined in relationship to various financial arrangements for services including prepaid group practice and fee for service, and whether the patient receives medical care from the centralized clinic or from its satellites. A major focus of the study is the way in which management of psychological disorder and social need by the mainstream medical care system affects patterns of subsequent utilizattion of medical resources and patient outcomes.

NIMH-CRB PSYCHOBIOLOGY DEPRESSION PROGRAM - CLINICAL

J. Endicott, New York State Psychiatric Inst., *722 W. 168th St., New York, New York* 10032 (R12 MH 23864-08)

The proposed new investigations will employ clinical psychopathological and genetic-familial methods in a sample of over 1,000 patients. Our efforts thus far have resulted in clarification of issues regarding classification, diagnosis, and etiology of affective disorders.

Psychopathological and genetic methods have been refined, especially those methods pertinent to testing the validity of nosologic classes. The results from our Pilot Clinical Study of 150 inpatients provide information as to frequency and intensity of symptoms and relative diagnostic occurrence of major nosologic classes within the affective disorders. Further progress in testing of hypotheses requires comprehensive and complex designs for studying large samples of patients, relatives and normals.

This research grant application proposes two major sets of studies - clinical psychopathology studies and genetic and family studies. The basic hypothesis common to sets of studies is that the affective disorders are heterogeneous as regards etiology, clinical features, and response to treatment. Precisely defined homogeneous nosologic classes, validated by multiple external correlates, will facilitate identification of risk factors for epidemiological studies, and verification of hypotheses as to etiology and pathogenesis.

FURTHER STUDY OF ESRD CASES AND CONTROLS

J.C. Anthony, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Mental Hygiene, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R03 MH 34213-01)

The proposed study is a pilot study which exploits an unexpected research opportunity, the current ready availability of more than 50 analgesic users who report near-daily use for periods of one year or more and who have agreed to participate in this study. Cooperating matched controls are also available.

The analgesics used by these individuals are paraaminophenol, salicylate, and salicylic in a variety of over-the-counter products legally purchasable without prescription. Sustained near-daily use of these products puts the user at increased risk of serious adversity, meets the federal definition for polydrug abuse and in some cases qualifies as drug dependence. However, very little is known about such users in the United States.

Interviews with users and controls will produce a more detailed description of the nature and course of sustained PAP-S-SA analgesic use than is presently available. They will also permit tests of several epidemiological and sociological hypotheses about the mode of spread and the genesis, maintenance and cessation of sustained use. The resulting information will be of great value in developing and applying programs of prevention to reduce the incidence and duration of such use.

The proposed study will make use of a case history without controls research design and a case-control research design to investigate the nature, course,

and mode of spread of such use, and to test the selected hypotheses. These hypotheses concern the intrafamilial and extra-familial environments of the users and controls (prior to onset of sustained use), and the status inconsistency of these subjects. In addition, the study offers a test of Charles Winick's 'sociological theory of the genesis of drug dependence.'

THE MENTAL HEALTH OF RESIDENTS NEAR THE THREE MILE ISLAND REACTOR - A COMPARATIVE STUDY OF SELECTED GROUPS

E. Bromet, University of Pittsburgh, Graduate School, *1028H Cathedral of Learning, Pittsburgh, Pennsylvania* 15213

There is a specific need to act with urgency in obtaining information about the impact of this nuclear incident as a near catastrophe upon the emotional and psychological health of the workers and citizens in the surrounding areas. It is imperative that information be obtained as quickly as possible about this incident because no research data are available in this specific realm of health activity. It is especially desirable to sample persons at special risk from an affected population in comparison with control subjects in order to provide factual evidence concerning: (a) the impact of stress from disasters and disastrous events; (b) variables which mediate the stressfulness of the event; and (c) the stability of the mental health changes over time. The objective of the study is to assess the mental health of persons exposed to a potentially disastrous event with a unique configuration of problems. The study should provide data which could be of use in understanding emotional reactions to extremely stressful events and, in particular, to gauging the mental health impact of such potentially catastrophic events as nuclear accidents. Specifically the contractor shall: 1. Develop methods of assessing the mental health functioning of high-risk groups in the population. 2. Identify variables which would be likely to mediate the stressfulness of the accident. These variables should include changes in social networks and perceptions of danger. 3. Conduct a study which will adequately assess responses at crucial time periods following a disastrous event. 4. Delineate the sampling frame and the means by which it is chosen. 5. Designate a comparison or control community and provide a rationale for such a choice.

ADOLESCENTS AND ADULTS AT GENETIC RISK FOR PSYCHOSIS

E.J. Anthony, Washington University, School of Medicine, Dept. of Psychiatry, *660 S. Euclid Ave., St. Louis, Missouri* 63110 (R01 MH 24819-06S1)

OBJECTIVE: To monitor the development of 193 children with a psychotic parent genetically at high risk for adult psychosis (experimental group) through a period of three years and to compare and contrast their development with 98 children of physically ill (mainly tuberculous) parents (comparison group) and with 138 children of parents who have experienced no significant mental or physical illness (control group), making a total of 429 children. All of these, currently ranging in age from 7 to 31 years, together with every member of the intact nuclear family group, have already been intensively and extensively studied along a number of different parameters (demographic, physical, psychophysiological, 'anthropological', psychiatric, psychological, experimental, and social), and based on these, prognoses have been made as to immediate and remote expectations of psychiatric disorder. The oldest children in all three groups (19 to 31 years and 186 in all) will be passing through a critical period for the genesis of certain types of psychosis, the incidence of which is less than 1 percent for the general population. Three index members have already sustained fully documented 'breakdowns' with hospitalizations, whereas the incidence in the comparison and control groups has so far been nil. These prospective investigations of psychosis in the making should throw light on the antecedent variables involved in prediction and help in the early recognition of vulnerable subjects. About one-third of the experimental group has undergone some form of preventive intervention, the efficacy of which is also under consideration.

ECONOMIC ANTECEDENTS OF BEHAVIORAL DISORDER

C.D. Dooley, University of California, Irvine Campus, Graduate School, *Irvine, California* 92664 (R01 MH 31499-02)

The proposed research will measure the relationship between changes in economic and demographic sub-groups of the population. The independent economic variables will include measures of change in the size and structure of the Washington County, Maryland economy as well as more intuitively predictive measures such as unemployment and inflation.

Several groupings of industrial sectors (e.g., basic industries, service industries) as well as the sum of all sectors will be used as independent measures. The dependent survey measures will include scores on stressful life events instruments, mood scales, psycho-physiological symptom scales and mental health case openings.

The life event, mood and symptom variables will be constructed from existing data collected in a 20-month epidemiological survey conducted by the Johns Hopkins School of Hygiene with NIMH funding. Case openings data are available from the providers of mental health services.

The strength of relationship between the dependent and independent measures wil be measured with cross-lagged correlational techniques for each demographic subgroup.

SCHIZOPHRENIC OFFSPRING FROM BIRTH TO ADULTHOOD

B. Fish, University of California, Los Angeles Campus, Neuropsychiatric Inst., Dept. of Psychiatry, *760 Westwood Plaza, Los Angeles, California* 90024 (R01 MH 31653-01)

This project will evaluate the adult outcomes and life histories of 24 offspring of schizophrenic and nonpsychotic mothers, who have been studied since their births in 1952-1953, and 1959-1960. The studies will test the hypothesis that specific neurointegrative disorders in infancy predict vulnerability to schizophrenia and to cognitive disorders characteristically found in schizophrenics and their first degree relatives. Neurointegrative disorder, abbreviated as Pandevelopmental Retardation (PDR), e.g., transient dysregulation of motor, visual-motor, and physical development, between birth and 2 years, was significantly related to maternal schizophrenia (X to the second power, p is less than .05) but not to obstetrical complications. The severity of PDR was significantly related to psychiatric morbidity (including schizophrenia) at 10 years (X to the second power, p is less than .01).

The studies proposed include (1) independent diagnostic evaluations of the rearing families, and the 24 subjects at age 20-23 years; (2) independent psychometric assessments of the subjects, their siblings, and their rearing families, including MMPI's and measures of disordered thinking, communication deviance, morbid thought content, and distorted visual-motor productions; (3) analysis of the changes in psychopathology and adaptation of the subjects, in relation to their life experiences; and, (4) analysis of adult outcome, in relation to (a) the chronicity of maternal schizophrenia; (b) the severity of PDR in infancy; and (c) the evidence of psychopathology and disordered communication in the rearing families (including 6 adoptive families). The data should facilitate comparison with the larger studies of children at risk, who have been followed for shorter periods. The long-term goal is to identify infants vulnerable to schizophrenia, and to study the underlying biological and pschological mechanisms during the period when intervention may be most effective.

AN EPIDEMIOLOGICAL STUDY OF ATYPICAL SCHIZOPHRENIA

M.T. Tsuang, University of Iowa, School of Medicine, Dept. of Psychiatry, *Jessup Hall, Iowa City, Iowa* 52240 (R01 MH 31673-02)

Our purpose is to gather comprehensive epidemiological data on 310 'atypical schizophrenics' in a longterm follow-up and family study. Procedures designed in the Iowa 500 Research Project, a study of the major psychoses now nearing completion at University of Iowa Psychiatric Hospital (IPH), give us highly effective methods for tracing and personally interviewing subjects as well as extensive procedures for data management and analysis.

In the Iowa 500 study, we used specified research criteria to select nuclear groups of 200 schizophrenics, 100 manics, and 225 depressives from patients consecutively admitted to IPH between 1934-1944. In the same population, 310 carried a chart diagnosis of schizophrenia but failed to meet the research criteria, chiefly for short duration of symptoms, episodic course, or mixed schizophrenic and affective symptoms. These 310 atypical schizophrenics and their families, plus a stratified random sample of 176 surgical controls and their families comprise the study sample. The control group provides baseline for comparison and maintains blindness in data collection.

Our aim is to identify homogeneous subgroups within the atypical schizophrenics by analyzing all follow-up and family data. We will compare these subgroups with any homogeneous subgroups we identify within the typical groups of schizophrenia and affective disorder. Using all available information we will identify homogeneous subgroups within the major psychoses. Finally, we hope to use the results of our analysis to refine the research criteria for selecting pure subgroups in future biological and psycho-social studies.

CHROMOSOME ABNORMALITY AND BEHAVIORAL VARIATION

S. Walzer, University of Massachusetts, Medical School at Worcester, School of Medicine, Dept. of Psychiatry, *419 Belmont St., Worcester, Massachusetts* 01604 (R01 MH 31897-03)

The research aims of this study are to relate the new areas of cytogenetics and human behavior genetics to problems in normal human development and psychopathology. We are investigating the nature of the relationship which might exist between the sex chromosome aneuploides in males (i.e., XXY, XYY) and subsequent personality development. Infants with these chromosome lesions and infants serving as controls were located through a chromosome screening of male neonates. These infants and children are being followed in a long-term developmental study with the aim of identifying reactive styles or developmental lags that might be related to the chromosome variations. The data, obtained through semistructured parental interviews (recorded verbatim) and direct observations of the child, are reduced to 16 operationally defined categories of behavior that represent the child's development and functioning in the most relevant aspects of psychosocial adaptation. Preliminary conclusions based on the systematic sampling method are tested independently by formal psychological testing and developmental assessments.

Considerable controversy has surrounded the issue of the possible relationship which might exist between certain sex chromosome variations and personality development. This controversy has resulted from the fact that much of the evidence suggesting

such a relationship has been obtained by surveying groups of individuals who demonstrated a particular personality deviation and finding an increased incidence of specific chromosomal aneuploidy among them. The natural history of unselected individuals who carry such variations remains largely unknown. Should long-term longitudinal studies of affected individuals reveal any developmental risk associated with the variation, this knowledge can be directed to helping these individuals overcome developmental lags and realize their full developmental potentials.

EPIDEMIOLOGY OF DEPRESSION AND HELP-SEEKING BEHAVIOR

R.R. Frerichs, University of California, Los Angeles Campus, School of Public Health, Dept. of Psychiatry, *405 Hilgard Ave., Los Angeles, California* 90024 (R01 MH 32267-02)

This research examines the occurrence of acute and chronic depression in a large, heterogeneous metropolitan area. The major objectives are to assess causal factors and outcomes associated with this condition, including physical health status, life event stressors, social support networks, health care utilization, and help-seeking behavior. Longitudinal panel data will be used in linear structural relationship models to assess the relative effects of reciprocal causation between mental and physical health status. In addition, the mediating effects of social support networks in buffering between stress and psychiatric health status will be examined.

With the use of a prospective study design, a random sample of 1,000 adults representative of the Los Angeles county population are initially being interviewed in a household survey and followed up quarterly by telephone interviews. The final interview will be either face-to-face or telephone interview, depending upon random assignment. A control group of 250 additional persons will be used at the final interview to investigate panel effects. The major instrument for classifying depression will be the NIMH CES-D scale.

This project will examine the role of social support systems on the use or nonuse of community mental health and general medical resources by individuals identified as depressed. The relationship between cigarette smoking, alcohol consumption, and use of medications and depressive symptomatology will be examined.

MEASURES OF UNTREATED PSYCHIATRIC DISORDER

B.P. Dohrenwend, Columbia University, College of Physicians & Surgeons, Dept. of Psychiatry, *630 W. 168th St., New York, New York* 10032 (R01 MH 10328-15)

The proposed research focuses on the central unsolved problem of psychiatric epidemiology, the problem of how to measure psychiatric disorders independently of treatment status in the general population. Its major aim is to test the sensitivity and specificity of the newly developed Psychiatric Epidemiology Research Interview (PERI) as a first-stage instrument to screen functional psychiatric disorders among adults in a demographically complex urban population.

To this end, two field operations would be conducted. In the first, we would investigate PERI's relationship to other potential screening instruments of a sample of 600 adults from the general population and calibrate PERI on a sample of 500 psychiatric patients with diagnoses of schizophrenia, affective psychosis, neurosis, anti-social personality, and other personality disorders. In the second field operation, we would examine PERI's relationship to two diagnostic instruments, the Present State Examination (PSE) and the Schedule for Affective Disorders and Schizophrenia (SADS). In this second study, interviews would be conducted with a full probability sample of 1400 adults from the general population. The research setting for these investigations would be Washington Heights, a section of Manhattan in New York City that surrounds the Columbia Presbyterian Medical Center. It is a demographically complex urban area containing large percentages of black and Puerto Ricans as well as members of more advantaged ethnic groups.

The results should provide a textbook example of the development and testing of a two stage procedure for case identification and classification. The findings should also be important for needs assessment and to the planning and evaluation of mental health service in Washington Heights.

PSYCHIATRIC IMPAIRMENT IN URBAN CHILDREN OVER TIME

T.S. Langner, Columbia University, School of Public Health, *600 W. 168th St., New York, New York* 10032 (R01 MH 18260-10S1)

Aims for the coming year include: 1. Development of a screening instrument with both concurrent and prognostic power for diverse outcomes by age-sex cohorts; 2. development of an instrument for measuring components of childhood depression; 3. investigation of stability and developmental change within environmental contexts; 4. investigation of historical change in child and parental behavior by ethnic background and sex of child; 5. determination of the extent to which the predictive power of the independent variables is a function of their stability; 6. comparison of causal models which postulate duration (additive effects over time) vs. change over time as critical in the developmental process; 7. development of the best causal models using path-analytic techniques for the major types of child pathology - anxiety, depression, aggression, antisocial behavior, and mentation problems; 8. construction of a more refined model of the stress-strain relationship, by utilizing specific stress scores for marital, parental, demographic, and physical illness stress; 9. examination of the age, sex, ethnic and SES moderators of the stress-strain relationship and predictive courses; 10. to better understand environmental moderators of change, investigate why improvement of poor or minority families does not improve child behavior outcomes, while deterioration of white affluent families doubles their children's poor outcome rate; 11. preparation of book manuscript which represents the major findings of the longitudinal analysis and a conceptualization of the types of psychopathology and types of environments of children and adolescents.

HEREDITY, ALCOHOL USE, TEMPERAMENT & CHD RISK FACTORS

E. Harburg, University of Michigan, Ann Arbor Campus, School of Public Health, Dept. of Epidemiology/Psychology, *Ann Arbor, Michigan* 48104 (R01 AA 02884-04)

The purposes of this study are to continue developing a survey approach to sampling sets of families in a given population to estimate the amount of genetic contribution to a variety of health-related variables for the purposes of (1) removing the effects of the genetic variance from alcohol-related traits and testing for environmental relations and (2) creating models for estimating heritability of given traits of interest.

The first objective then is methodological: (1) to validate the 4-person Family Set Method by use of genetic markers, and (2) vary the composition of Family Sets to include multiple sibs and first cousins and compare results on genetic markers to simple four-person Sets. The second objective would be to estimate the roles of nature-nuture in alcohol usage, cardiovascular health-risk factors, and specific temperaments, e.g., Extraversion-Introversion and Neuroticism. The third objective is to statistically standardize or remove the genetic effects, if any, and test for relationships among alcohol usage, temperaments, family behavior, health risk factors and demographic categories.

The study sample will be Family Sets (Index, sib, first cousin, unrelated person) drawn from (1) Cardiovascular Exam I (1960-61), and (2) from Cardiovascular Exam II (1963-65). About 265 Sets (after losses) are available with questionnaires collected in 1977 with data on alcohol usage, temperament, and health habits.

A NATURALISTIC STUDY OF FAMILIES IN TREATMENT

J.I. Ablon, University of California, San Francisco Campus, Langley Porter Neuropsychiatric Inst., *401 Parnassus Ave., San Francisco, California* 94122 (R01 AA 00180-03)

The proposed research has as its major objective the investigation of the relationship between religion, ethnicity, and family response to alcoholism. Within certain religious and ethnic groups I will: a) examine the role of drinking patterns in both conflicted and non-conflicted families of similar socio-economic characteristics for an assessment of how drinking patterns relate to the totality of family interaction and life style, and under what conditions alcohol consumption becomes a 'problem'; b) compare conflicted families where there is no alcohol problem with conflicted families of similar socio-economic characteristics where there is an alcohol problem. One result of this inquiry will be a clearer understanding of the role that problem drinking plays in family conflict.

Field methods to be used will be in-depth, on-going interviewing of 60 selected families in two religious groups. Participant-observation activities in the two parishes will also be used to a limited extent.

PROBLEM DRINKING, DELINQUENCY, AND MATURATIONAL REFORM

S.R. Burkett, Washington State University, Graduate School, Dept. of Sociology, *Pullman, Washington* 99163 (R01 AA 02620-04)

The study investigates the dimensions and determinants of adolescent problem drinking and delinquency involvement. Of principal concern is the study of social maturational development and reform as this relates to involvement in and the cessation of adolescent problem drinking, and the impact of legal intervention in the lives of adolescents. The major focus is upon differential degrees of involvement in and attachment to conventional social institutions and people, and commitment to conventional educational and occupational career lines. Specifically, a major objective is to provide longitudinal baseline data on the developmental nature of adolescent ties to the family, the school, religion, the world of work, the community and the peer group. A second major objective is to establish empirical links and associations between these ties, various personal controls and belief systems relating to the law, religion, and perceived consequences of alcohol use and abuse, behavioral variables, and problem drinking. The research is a panel study involving a cohort of high school youth over a four-year period. Data sources include a questionnaire survey, and scho l and juvenile court records. Primary goals include theoretical development and refinement and policy recommendations.

ALCOHOL INTAKE IN PREGNANCY AND OFFSPRING'S DEVELOPMENT

A.P. Streissguth, University of Washington, School of Medicine, Dept. of Psychiatry & Behavioral Sci, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (R01 AA 01455-05)

In 1974 a longitudinal prospective study was undertaken to investigate the effects of social drinking on the outcome of pregnancy and the health and development of the offspring. Women who had registered for prenatal care by the 5th month of pregnancy were interviewed regarding their use of alcohol, nicotine, caffeine and drugs.

A variety of behavioral and developmental measures were obtained on subjects of these infants, including operant learning studies, Brazelton Neonatal Behav-

ioral Assessments, naturalistic observations and dysmorphology examination. The Bayley Scales of Infant Mental and motor Development were given when the follow-up cohort of 500 were 8 and 18 months of age.

The present project will examine the follow-up cohort of 500 children, at age four years. The following types of assessments will be used: Intelligence tests, behavior rating scales, psychiatric check-list, health questionaire, anthropomorphic measurements, naturalistic observations, motor tests, and dysmorphology examinations.

The 4-year old data will be studied in terms of maternal alcohol use (adjusting for smoking, caffeine use, and drugs) and in terms of the relationship to earlier behavioral and developmental indices.

MATERNAL DRINKING, FETAL DAMAGE, AND CHILD DEVELOPMENT

J.J. Alpert, Boston City Hospital, *818 Harrison Ave., Boston, Massachusetts* 02118 (R01 AA 02446-04)

The Maternal Drinking, Fetal Damage and Child Development Project has two primary goals: (1) to study the relationship between maternal drinking patterns and the risk of fetal malformations, concentrating particularly on the fetal alcohol syndrome, and (2) to explore the relationship between alcohol consumption and subsequent child development.

These data should provide a more complete understanding of the risks of maternal drinking during pregnancy, and of the fetal alcohol syndrome, its nosology, frequency and determinants. This study is being conducted at a municipal hospital which serves a population with high rates of alcohol consumption. All of the women who deliver at the Boston City Hosptial are interviewed about alcohol, use of other drugs, cigarettes, nutritional and health status before and during pregnancy. This cohort of approximately 2000 women includes women from all of the neighborhood health centers. In one part of the study, the 600 women per year who register at the Prenatal Clinic of the Boston City Hospital are interviewed. Intervention is offered for those women who drink heavily.

The larger cohort is being followed using both interviews and observation to assess general and neurological development, and mother-child interactions, in the first two years.

A PROSPECTIVE STUDY ON FETAL ALCOHOL SYNDROME

S. Miller, Case Western Reserve University, School of Medicine, Dept. of Psychiatry, *2109 Adelbert Rd., Cleveland, Ohio* 44106 (R01 AA 03282-02)

The proposed project is a six year, prospective study on the fetal alcohol syndrome. The overall goals of the study are to determine the incidence of fetal abnormalities secondary to excessive alcohol consumption, and to examine the efficacy of intensive alcoholism treatment in reducing the frequency of fetal anomaly. Four phases are proposed. The first is a Discovery and Screening Phase (2 years) using the Michigan Alcoholism Screening Test (MAST) as part of the high risk screening conducted by the prenatal clinic at Cleveland Metropolitan General Hospital (CMGH). During this period, pregnant women scoring positively and negatively on the test will be identified. Concurrently, the Treatment and Prenatal Monitoring Phase (2 years 9 months) will consist of randomly assigning positive MAST responders to high intensity and low intensity treatment and an equal number of negative responders to a non-alcoholic comparison group. In the low intensity group, routine prenatal monitoring and Alcoholics Anonymous are the only treatment modalities to be employed. In the high intensity treatment group, identified women will be enrolled in an intensive abstinence-oriented treatment program consisting of individual counselling, specialized group counselling and referred to Alcoholics Anonymous. Fetal outcome will be assessed in the low-intensity treatment group, the high intensity treatment group, and the non-alcoholic comparison group. Subgrouping will determine the results for individuals who accept or reject treatment. The prenatal monitoring will consist of monthly evaluations of volume and pattern of alcohol intake using the Volume Pattern Index; social, physical and economic factors using the Data Base Sheet for Alcohol Related Problems; monthly dietary assessment, monthly blood alcohol levels and routine prenatal monitoring as part of the antenatal clinic visit to CMGH through parturition. The Postnatal Outcome Analysis Phase (3 years) will involve physical, neurological and psychological examination of all study infants (alcohols and controls) to be done at birth, and ages 6 months, 1 year, 2 years, and 3 years. The Statistical Analysis Phase (9 months) will be major analysis on the data collected during the first three phases of the study. Quarterly reporting will occur throughout the six years of the study.

A LONGITUDINAL STUDY OF CHILDREN OF DRINKING MOTHERS

J.W. Kuzma, Loma Linda University, School of Health, Dept. of Biostatistics & Epidemiology, *Loma Linda, California* 92354 (R01 AA 00688-06)

The interest in the effects of drinking during pregnancy has grown rapidly following the early publications on the fetal alcohol syndrome by Jones and Smith in 1973. The results of various studies to date suggest an adverse relationship of heavy maternal alcohol use during pregnancy on the offspring. There still remains, however, some unanswered questions such as: 'What is the effect of moderate drinking on the offspring? What are the possible synergistic effects of alcohol use with other substances such as smoking? What are the long term development effects of maternal alcohol use on the offspring? Does termination of maternal drinking during the early stages of pregnancy reverse possible adverse effects on the offspring? A five-year prospective study of 1,320 children ages 2 to 5 is proposed to provide information to help answer these questions. The 1,320 children are to be selected from an ongoing study of 10,000 pregnant women on whom we already have extensive prenatal, labor delivery and birth information. For each participate we will annually assess the home environment, parent-child interactions, demographic and psychosocial factors by means of a home interview. Physical and mental characteristics on each child will be assessed by a pediatric nurse and a psychometrician at the first and fourth year at a visit to our clinic. The study design calls for three different comparison groups which will provide data to determine the role that alcohol use during pregnancy played on subsequent development characteristics. By being able to provide data concerning the possible harmful effects of drinking during pregnancy on the offspring, information will be made available that can be used to initiate prevention programs to hopefully reduce morbidity and disability and cut the cost of care of premature infants in the community.

ALCOHOLISM TRANSMISSION VIA FAMILY RITUAL

S.J. Wolin, George Washington University, School of Medicine & Health Sciences, Dept. of Psychiatry & Behavioral Sciences, *2121 Eye St. N.W., Washington, District of Columbia* 20037 (R01 AA 01454-06)

This continuation application proposes a second study on family factors involved in the intergenerational transmission of alcoholism. In the initial study, families with alcohol abuse in two generations--transmitters--have been compared with families having only parental generation affected--non-transmitters. The characteristics of ritual behavior in daily life have been compared in both groups. The transmitter group has been found to develop a preponderance of rituals involving alcohol abuse, subsuming the normal ritual functions in family living. These families have been labelled 'subsumptive,' distinguishing them from 'distinctive' families where normal ritual behaviors do not include alcohol abuse. In transmitter families selective sibling involvement appears related to a second family factor--the continuation or rejection of the family's heritage. This is particularly true at the time of offspring marriage when the selection of a family identity for the new couple will normally allow one origin family or the other to predominate as the family of heritage.

In the proposed study we have revised our structured interviews and criteria for subject population to perform a within-family sibling comparison. The objective will be to assess the likelihood that each married child will repeat in the successive generation his parent's alcoholism. Siblings will be compared as to the subsumptiveness of their origin families and their family identity selection. Subjects will include thirty transmitter families with approximately ninety married couples and their parents, when available. Individual and conjoint couple interviews will be standardized and a manual will be prepared for rating origin family type and family identity selection. Drinking patterns of all family members will be separately assessed and scaled. A rating of the likelihood for alcoholism transmission for each sibling will then be compared with actual drinking behavior to evaluate the relationship between alcohol abuse rituals, family identity and the recurrence of alcoholism.

ALCOHOL USE AND ABUSE AMONG URBAN WOMEN

D.V. McQueen, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Behavioral Sciences, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 AA 04313-01)

The proposed research represents an exploratory study concerned with documenting the use and abuse of alcohol and alcohol-related problems among urban women. The major goal is to provide reliable and valid estimates of what is increasingly recognized as a growing public health problem among women. Ultimately this will lead to more empirically based planning for services to women with alcohol problems. In essence, our goal is to provide a clearer picture of the epidemiology of alcohol problems among women. Specifically, we propose to: (1) develop new estimates of the prevalence of problem drinking focusing upon context-specific Q-F estimates and to measure the extent of 'hidden' drinking among women; (2) to compare the more traditionally used alcoholism prevalence estimator derived rates of alcohol problems with these newly developed measures; and (3) to account for the part which newly emerging sex roles among women play in alcohol abuse and alcohol problems.

The approach we propose is unique in that the methodology itself will be under scrutiny. Utilizing recently developed and validated telephone survey techniques, a survey will be conducted, consisting of two phases: a random telephone sample of 1,100 households will be utilized in order to screen women who are at 'risk' for alcohol problems, evidenced by moderate to heavy drinking, thus identified, these cases will be subjects for an intensive home interview. A special subsample of non-telephone households will be drawn to maintain a representative sample. Further, we will validate the use of responses obtained by telephone interviews with responses given in personal interviews, leading, ultimately, to more reliable and valid methods of estimating the prevalence of alcohol problems among women.

2.0288,

COMMUNITIES, ALCOHOL POLICIES AND CIRRHOSIS MORTALITY

W. Mandell, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Mental Hygiene, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 AA 04347-01)

The present study will examine the relationship between alcohol control policies, characteristics of counties, and sex and race specific liver cirrhosis mortality. Two methods of analysis, epidemioiogic case control and multiple regression will be compared to determine whether similar independent variables will be identified as associated with the dependent variable. The research will produce the following products: A compilation of the alcohol control policies of the 3,095 U.S. counties and 100 independent cities, an analysis of the relationship between county characteristics and their control policies, and an analysis of the interaction between con-

trol policies and community characteristics as they together affect cirrhosis mortality.

FETAL ALCOHOL SYNDROME WORKSHOP

A.P. Streissguth, University of Washington, School of Medicine, Dept. of Psychiatry & Behavioral Science, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (R13 AA 04587-01)

We propose a workshop of about 75 scientists currently involved in research on fetal alcohol syndrome (FAS), teratogenic effects of alcohol and/or public health issues relating to alcohol use and abuse during pregnancy. The purpose of the workshop is to document the current state of knowledge regarding the teratogenic effects of alcohol and to propose new directions for future research.

We propose a 2-1/2 day workshop including the following sessions: Clinical aspects of FAS, human and epidemiologic studies, animal teratology and behavioral studies, biochemical studies, reports from 4 NIAAA-funded prospective studies. We propose to bring some researchers from out of the U. S in order to improve international understanding and cooperation in this important area.

Proceedings will be compiled in a book and submitted for the NIAAA Research Monograph Series.

CENTER FOR THE STUDY OF ALCOHOLISM

R.U. Massey, University of Connecticut, Health Center, School of Medicine, Dept. of Psychiatry, *Farmington Ave., Farmington, Connecticut* 06032 (P50 AA 03510-03)

In a series of related and interrelated studies, we propose to examine genetic, behavioral, biochemical and psychopathological aspects of alcoholism. In a follow-up study of factor analytically derived typologies of male and female alcoholics, we propose to develop a multidimensional prediction model of treatment outcome empirically derived from an extensive data base of behavioral, sociological, psychopathological, demographic and pedigree assessments obtained from large sample of alcoholic patients. In some individuals, this will include a systematic assessment of tolerance. Patient outcome will be assessed periodically utilizing a broad range of outcome criteria and using a life insurance table approach to the assessment of 'risk' and 'treatment impact'. Separate prospective studies of antidepressant and lithium treatment will be carried out in a similarly designed format.

In addition to pedigree assessments, we propose to carry out a comparative prospective longitudinal study of young adult children of alcoholic and nonalcoholic individuals.

Finally, studies on the importance of stimulus control of drinking behavior in alcoholics and normal subjects will focus on respondent and operant conditioning in alcoholics. These studies will also be carried out in a clinically relevant context.

Findings from the proposed work should contribute to improved alcoholism treatment and prevention strategies and to greater understanding of the multivariate nature of the disorder.

SOCIAL EPIDEMIOLOGY OF ALCOHOL PROBLEMS

W. Winkelstein, University of California, Berkeley Campus, School of Public Health, Dept. of Social & Admin Hlth Sciences, *Berkeley, California* 94720 (P50 AA 03524-02S1)

Four separate research projects are a part of the research center grant: 1. A study of community responses to alcohol problems involves description and analysis of all agencies dealing with alcohol problems in a study community. Formal treatment agencies are included, as are organizations such as AA, but also included are police, clergy and others who encounter alcohol problems. Community surveys of general populations will be included if possible. 2. An Historical Study of Alcohol Control policies in the U.S. is being undertaken using a combination of historical research methods and analysis of various official records. The intent is a description of the actors and interests who have played significant roles in the development of U.S. policies regulating alcohol use in the years since the turn of the century. 3. The Study of the Structure and Political Economy of the Alcoholic Beverage Industry makes use of published and unpublished data on production and distribution of alcoholic beverages plus materials from trade publications, various secondary sources, etc., to describe the interplay of production, consumption and regulation in the years since the repeal of Prohibition. 4. A study of Alcohol Use and Casualties is concerned with the relationships between alcohol use and such things as accidents, crime, and other casualties. Both aggregate level and individual level data (as from surveys) will be used to describe empirically the relationships among the rates of consumption and problems.

Projects 2-4 are part of an international study coordinated by WHO European Office which coordinates research on these same topics in Canada, Finland, Ireland, Japan, Netherlands, Poland, Switzerland and in the U.S.

THE ETIOLOGY OF ALCOHOLISM

J.A. Carpenter, Rutgers the State University of New Jersey, New Brunswick Campus, Center for Alcohol Studies, *Old Queens Bldg., New Brunswick, New Jersey* 08903 (P50 AA 03509-03)

This prospective longitudinal study of the etiology of alcoholism began in its second year to accept its first participants, participants selected through random telephone interviews, followed by home visitis where consent was obtained to a full day's on-site visit. The participants, expected to number 325 in this budget year, provide personal data in the social-cultural, psychological, cognitive-perceptual and biological realms; the particular measures used were chosen to highlight differential responses hypothesized to play an etiological role in drinking problems. The study is projected to enlist over 5,000 adolescents to be seen at 3-year intervals until the age of 24, and thereafter at 6-year intervals. An additional 600 new participants are slated to be interviewed and tested in year 3. About 8,600 telephone interviews were necessary to obtain 325 subjects, representing more than one-third of age-eligible respondents; analysis of demographic and other data from this process reveals that participants do not differ from age-eligible non-participants, nor from the larger sample of ineligibles. This study is expected to identify predictive factors predisposing to alcohol abuse and alcoholism: such identification should make possible targeted intervention of persons at risk, prevention of development of alcoholism its goal. In the shorter term, the knowledge gained of the nature and extent of alcohol problems experienced by adolescents as they transit toward adult drinking patterns will help in the formulation of appropriate prevention strategies for specific problem complexes.

EPIDEMIOLOGY OF CHANGES IN ALCOHOL CONSUMPTION

H.A. Mulford, University of Iowa, School of Medicine, Dept. of Psychiatry, *Jessup Hall, Iowa City, Iowa* 52240 (R01 AA 03829-02)

An investigation of the conditions and consequences of a dramatic increase in per capita alcohol sales in Iowa since 1958. A cross sectional survey replicating baseline surveys conducted in 1958 and 1961 will investigate changes in: 1) per capita consumption of alcohol; 2) the quantity/frequency dimensions of drinking patterns; 3) the dimensions of problem drinking; and 4) their social and attitudinal concomitants.

Additionally, large seasonal variations (both increases and decreases) in per capita consumption and its correlates will be investigated with a three stage, 12 month panel study. This will allow us not only to compare short with long term changes in consumption, but also to begin to untangle the complex causal chains among the factors affecting alcohol consumption, drinking patterns and problem drinking.

DRINKING PATTERNS AMONG DISTRICT HIGH SCHOOL STUDENTS

F.S. Tesmer, Aurora Research Corp., *1029 Vermont Ave. N.W., Washington, District of Columbia* 20005 (R01 AA 03978-02)

The purpose of this study is to conduct an exploratory study of drinking patterns among District of Columbia high school students. The study is designed to: (1) provide detailed descriptions of drinking behavior by high school students in order to establish firmer norms for the prevailing drinking or non-drinking customs and norms; (2) examine some of the factors which influence or promote alcohol use, abuse or non-use among high school students in Washington, D.C.; (3) identify some of the problems associated with drinking; (4) generate descriptive baseline data required to develop treatment model(s) which considers the unique normative drinking patterns of high school students in the District of Columbia; and (5) make long-term predictions of the correlates and possible consequences of changes in specific types of drinking problems or potential problems.

The survey sample consists of a stratified random sample of approximately 300 students, enrolled in District of Columbia public high schools. The sample will be drawn from a population of approximately 23,033 students. The primary method of data collection will be personal or face-to-face interviews. Data reduction procedures will include frequency distributions, ANOVA and factor analysis.

ALCOHOL AND THE STANDING ROCK SIOUX TRIBE

J.O. Whittaker, Pennsylvania State University, Capitol Campus, Graduate School, Dept. of Psychology, *Rte. 230, Middleton, Pennsylvania* 17057 (R01 AA 04078-01)

The proposed research has several objectives. Among these are: (a) to establish more clearly the cultural variables related to symptoms of alcohol dependence; (b) to document changes in the incidence of problem drinking and/or alcoholism in the Standing Rock Sioux Tribe over the past sixteen years; and (c) to compare the pattern of drinking with other major reservation tribes in the U.S., such as the Navajo.

Using an interview schedule modified from the one used in a previous study by the Principal Investigator, the actual interviewing will be done by Indian, rather than White, interviewers. Each interview will be tape-recorded and later transcribed. No record of the respondent's name will ever be made and all tapes will be destroyed following their transcription. Approximately 10 percent of the total reservation population will be interviewed (of those over 15 years of age). The total sample will include 200 subjects, equally divided between male and female. The number of subjects will be in the same proportion for sex, age, and geographical distribution in the sample as in the most recent census figures for the entire reservation population.

Statistics on the physical symptoms of alcoholism will also be collected by the Principal Investigator from the U.S.P.H.S. hospital on the reservation. In addition, 20-30 in-depth interviews will be conducted by the Principal Investigator with selected reservation residents. Finally, there will be an informal comparison of the findings with personnel on the large Navajo reservation in Arizona by the Principal Investigator.

NUTRITIONAL FACTORS IN THE FETAL ALCOHOL SYNDROME

A.M. Huber, Eunice Kennedy Shriver Center for Mental Retardation, *200 Trapelo Rd., Waltham, Massachusetts* 02154 (R01 AA 03289-03)

The clinical studies are designed to identify the possible role of nutritional deficiencies, specifically vitamin and trace metal deficiencies in the production of abnormalities in offspring of women with excessive alcohol intake during pregnancy, to obtain information which may lead to possible prevention of the injurious effects of alcohol ingestion by pregnant mothers on the developing fetus.

In laboratory studies the role of trace elements and vitamins in the etiology and pathogenesis of the abnormalities in the fetus due to alcohol ingestion is being investigated.

GENETIC AND EXPERIMENTAL ANTECEDENTS OF ALCOHOLISM

D.W. Goodwin, University of Kansas, Medical Center, School of Medicine, Dept. of Psychiatry, *39th St. & Rainbow Blvd., Kansas City, Kansas* 66103 (R01 AA 03448-02)

Many studies have indicated that children of alcoholics are at high risk for alcoholism. Based on adoption studies, it appears that the susceptibility to alcoholism among the children of alcoholics exists whether the children are raised by their biological alcoholic parents or by non-alcoholic adoptive parents. Perhaps 20 to 25% of the male offspring of alcoholics become alcoholic, based on studies conducted over the past century. The goal of this study is to identify predictors of alcoholism among the sons of alcoholics, with the first stage of the study being conducted before the sons have had extensive experience with alcohol. Numerous differences have been reported between alcohlics and nonalcoholics, but interpretation of these differences has been difficult because they may be accountable to the toxic effects of alcohol itself. This study contravenes this problem by studying children of alcoholics before they have drank enough to produce significant biological and psychological changes. The subjects were located through Danish registers as having had at least one parent hospitalized with a diagnosis of alcoholism. A matched control group consists of individuals without such a history. All of the subjects were a part of a large perinatal study conducted some 17 years ago in Denmark of 9,000 consecutive deliveries at a single hospital. Data gathered will be based on interviews, psychological tests, records, information from families and psychophysiological and electrophysiological measures. The first three years of the study consists of gathering the basic information about the subjects with an anticipated follow-up period of 10 or more years.

PATHOLOGIC & TOXIC EFFECTS OF ALCOHOL

J. Wolf, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Clinical Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (P50 AA 03508-03S1)

Our interdisciplinary team (with expertise in hepatology, gastroenterology, biochemistry, pathology, cardiology, community medicine, endocrinology, genetics, immunology, neurology and nutrition, pharmacology, psychiatry, surgery) will conduct studies in patients as well as in our experimental models of alcoholic injury in rats and baboons in which liver lesions seen in the alcoholic (including cirrhosis) were reproduced. We plan to assess biochemical differences between alcoholics and nonalcoholics and to apply these findings to the validation of a blood test for alcoholism. Alterations of alcohol metabolism and the role of protein retention, acetaldehyde toxicity and immunological reactions in the development of alcoholic liver diseases will be determined. The nature of the abnormality in collagen metabolism will be evaluated. We plan to study the pathogenesis of alcoholic fatty liver and to develop a blood test which might enable us, in a population of heavy drinkers, to detect those whose alcoholic intake has resulted in a significant liver damage beyond the fatty liver stage. We will also try to define a precirrhotic lesion which might allow us to predict which alcoholics might develop cirrhosis, thoreby enhancing our effectiveness in the prevention of this complication. Other attempts at prophylaxis will include the definition of nutritional and preexisting medical conditions that favor the development of cirrhosis and portal hypertension when associated with heavy drinking. Pathogenesis of alcohol induced muscle, intestinal and pancreatic lesions will be assessed, including the carcinogenic role of alcohol. Involvement of microtubular alterations in chromosomal abnormalities and their link to the fetal alcohol syndrome will be determined. Androgen and estrogen abnormalities associated with alcoholism will be evaluated through measurements of hormone levels and clearance rates in the blood and enzyme activities in the liver. Our baboon model will be made available as a resource to other interested investigators.

DRINKING PATTERNS AMONG AMERICAN INDIAN WOMEN

D.E. Miller, Native American Resource & Research Associates, *Box 88, Pauma Valley, California* 92061 (R01 AA 04134-01)

The proposed research will center on four issues: (1) patterns of alcohol use among American Indian women of child-bearing age; (2) the effects of 'alcoholic' drinking upon the women and the health or development of their children, with special attention to 'fetal alcohol syndrome'; (3) the relationship between drinking behavior and anomie; and (4) the relationship between drinking behavior and identification with Indian tradition.

The study will perform a secondary analysis of comprehensive data previously compiled in a study of Indian child-bearing practices that used a sample of 100 Indian mothers with young children, half of them on reservations near San Diego, California, and the other half in the San Francisco-Oakland metropolitan area. The research instrument used in the previous study contained scales for measuring 'preoccupation with alcohol,' anomie, and attachment to Indian tradition. These scales, along with the empirical data, including data on the children's health and development, afford an adequate data base for the proposed analysis.

A PANEL STUDY OF ADOLESCENT SUBSTANCE ABUSE CAREERS

E.R. Morrissey, University of Washington, Alcoholism & Drug Abuse Inst., *Seattle, Washington* 98195 (R01 DA 02151-02)

This research is a continuation of a project consisting of a follow-up of 1473 adolescents who have been previously interviewed regarding drug and alcohol use patterns and related problems. The project will isolate factors which contribute to the development of substance abuse problems in late adolescence and to their persistence into early adulthood. All of the high risk subjects, originally contacted when they were referred for alcohol counselling or held in juvenile court detention, are being interviewed in the follow-up study. The treatment agencies in which the baseline data were collected will cooperate in recontacting their clients.

Four specific sets of factors will be examined as predictive of stable heavy alcoiol and drug intake and of the development of resultant problems. Independent variables hypothesized to relate to substance abuse outcomes are: (1) prior psychiatric diagnoses; (2) seriousness of deviant history; (3) initial levels of substance intake and related problems and (4) sex role attitudes and behaviors. The effects of these independent variables will be examined controlling for the type of intervention to which the youths were initially subjected, and for demographic characterisics.

An assessment of the effects of these variables will allow for: (1) an evaluation of the relative importance of psychiatric and social histories in the development of symptoms of alcoholism or drug abuse in early adulthood; and (2) the establishment of psychiatric diagnostic criteria for alcoholism and drug abuse which will be useful in screening youthful populations.

DETECTION OF MUTAGENS IN BODY FLUIDS OF SMOKERS

G.J. Mc Garrity, Inst. for Medical Research, Dept. of Microbiology, *Copewood St., Camden, New Jersey* 08103 (R01 DA 02488-01)

Cigarette smokers constitute the largest population exposed to environmental mutagens and the largest population of drug abusers. Controlled, prospective studies have been designed to directly and indirectly detect mutagens in urine and blood of smokers and to determine if there is a genetic response to exposure to mutagens in cigarette smoke. Urine samples will be concentrated and assayed by the Ames procedure. Sister chromatid exchange, unscheduled DNA synthesis and chromosomal analysis will be performed on short term lymphocyte cultures. The results of Ames and the various cytogenetic assays will be compared to determine the relative effectiveness of the different assay systems. Results of these studies will yield meaningful data on the effectiveness of various assay systems to detect mutagenic activity in body fluids, and the role of host response to standard doses of mutagens in cigarette smoke. Procedures developed in this study will have practical application to assays for mutagens other than cigarettes.

INHALANT ABUSE AMONG YOUNG NATIVE AMERICANS

E.R. Oetting, Colorado State University, School of Natural Sciences, Dept. of Psychology, *Fort Collins, Colorado* 80523 (R01 DA 01853-02)

Two related research projects on drug use among Native American young people will be done--a longitudinal study and a cross-sectional survey. The longitudinal study will determine how drug use changes over time. Approximately 1800 young people from three large, geographically distinct tribal groups in grades four through twelve will be surveyed during the Spring semester of 1981 and later during the Fall semester of 1982. Each drug use type (for example, those who use both inhalants and alcohol heavily in the 7th grade) will be followed up to determine what their patterns of drug use are 2 1/2 years later. A wide range of factors will be assessed to identify

characteristics that predict later consequences, i.e., increased drug involvement or later avoidance including: age of first use, type and extent of early drug use, family and peer influences, reasons for using drugs, identification with Native American culture, anxiety/unhappiness, attitudes to deviance, etc. The cross-sectional study will be in in-depth examination of inhalant and PCP epidemiology, since increases in both are expected during the next three years. Geographic isolation and cultural characteristics of at least 12 tribal groups sampled over three years will be examined to test hypotheses about how drug use spreads across reservations. PCP and inhalant use will be examined in the context of other drug use and correlated with the above list of factors to determine what attitudes and social surrounding characteristics relate to their use. The total for both studies will be approximately 5120.

U.S.-MEXICO PROGRAM OF RESEARCH IN INHALANT ABUSE

M. Korman, University of Texas, Health Science Center at Dallas, Graduate School of Biomedical Sciences, Dept. of Psychology, *5323 Harry Hines Blvd., Dallas, Texas* 75235 (R01 DA 01977-01A1)

This investigation proposes to study various groups of U.S. and Mexico inhalant users in a series of joint and related studies focusing on young adults. We aim to: 1) Complete an ethnographic study of inhalant use consisting of (a) an analysis of individual users, (b) an analysis of the social context; (c) an analysis of the institutional framework which interfaces with inhalant users. 2) Evaluate the relationship of inhalant use and aggressive behavior; investigate aggressive responses in relationship to such variables as degree of frustration, range of coping strategies available, degree of impulsivity. Examine a number of personality variables to assess underlying psychological mechanisms. 3) Investigate the relationship of the development of tolerance for inhalants to patterns of inhalant use. 4) Describe the extent of psychological dependence upon, and commitment to inhalant use. Relate to sex and ethnic differences. 5) Quantify the extent of physical dependence upon inhalants and relate to patterns of use; chart clinical picture of withdrawal. 6) Evaluate biomedical and neuropsychological status of heavy inhalant users in comparison to other drug users.

SUBSTANCES ABUSE - SPONTANEOUS ABORTION & FETAL DEFECT

Z.A. Stein, New York State Psychiatric Inst., *722 W. 168th St., New York, New York* 10032 (R01 DA 02090-01)

The study will examine the role of the following substances in relation to spontaneous abortion and fetal defect: alcohol, aspirin, heroin, marijuana, methadone, and tranquillizers. Two approaches will be taken.

First, substances which are associated with spontaneous abortion will be identified through a comparison of the karyotypic and morphologic characteristics of the conceptions of exposed and unexposed parents.

For each substance, the duration of exposure, the timing in relation to conception and the parent involved will be considered.

The proposed study will extend the fieldwork, modify the interview, and refine the analysis of a prior epidemiological study.

2.0307,

SUBSTANCE ABUSE AMONG HYPERACTIVE BOYS AT ADOLESCENCE

J.P. Loney, University of Iowa, School of Medicine, Dept. of Psychiatry, *Jessup Hall, Iowa City, Iowa* 52240 (R01 DA 02134-02)

This is a comprehensive longitudinal study of the use and abuse of drugs and alcohol in a sample of 135 hyperkinetic boys who were (a) seen for outpatient psychiatric evaluation in the five-year period between 1967 and 1972; (b) subsequently treated with a CNS stimulant drug (methylphenidate); and (c) followed up at adolescence by the present investigator with an extensive battery of tests, interviews, questionnaires, forms, and ratings.

In the first stage of the study, data are drawn from a multivariate computer archive maintained on these boys, and a series of questions about the prevalence of substance use is being investigated. Predictors of adolescent drug and alcohol use and abuse are also being identified, and the covariation of alcohol use, drug use, and other norm-violating and illegal acts (e.g., aggression and delinquent behaviors) is being determined.

In the second stage of the study, an additional sample of 100 hyperkinetic boys is being followed up at adolescence. These are boys who were seen for outpatient psychiatric evaluation in the five-year period between 1972 and 1977 but who (because of a change in 1972 of the clinic's administration and treatment personnel) were not treated with CNS stimulant. Data are being coded so that the drug-treated and untreated hyperkinetic boys can be equated on age, socioeconomic status, and kind and severity of hyperkinetic symptoms. Prevalence and convariation of drug and alcohol abuse in the untreated hyperkinetic samples will then be determined and compared with data from the drug-treated and normal groups. In addition to these descriptive analyses, the cross-sectional and longitudinal predictors of substance use will be identified.

A general aim will be to locate substance use and attitudes within a larger matrix of health threatening and norm-violating behaviors and their treatment and environmental antecedents. Data collection, coding, and storage; statistical analysis; and dissemination will take place throughout each of the three years of this study.

LONGITUDINAL STUDY OF TEENAGE AND YOUNG ADULT DRUG USE

G.M. Smith, Massachusetts General Hospital, *32 Fruit St., Boston, Massachusetts* 02114 (R01 DA 00065-08)

Our objective is to study antecedents and sequelae of drug use among teenage students and young adults by analyzing a comprehensive, 13-year longitudinal data base collected from 3,200 subjects. Those subjects were in grades 7-12 when our study began in 1969. Between 1969 and 1979, measures were obtained regarding use of illicit drugs, alcohol, and cigarettes; attitudes toward and knowledge about drug users; attitudes toward cigarette smoking and cigarette smokers; personality; grade point average; school attendance; and school suspensions. Follow-up studies to be performed by mailed questionnaire during 1980 and 1981 will collect information regarding post high school substance use and significant life events. Topics covered will include current and past use of illicit drugs, alcohol, and cigarettes; education, work, and military experience since high school; personality; social and family adjustment; physical and psychological health; hospitalization; accidents; and contacts with the criminal justice system. A second mailed questionnaire will be sent to 700 subjects, selected from the sample of 3,200 to represent well-delineated subgroups defined by substance use and non-use.

RESEARCH CENTER - STUDIES OF DRUG DEPENDENCE AND ABUSE

C.R. Schuster, University of Chicago, School of Medicine, Dept. of Psychiatry, *5801 S. Ellis Ave., Chicago, Illinois* 60637 (P01 DA 00250-08)

The Drug Abuse Research Center has continued: 1) to provide a formal structure designed to encourage the cooperation of basic research scientists and clinical researchers in problem-oriented research, 2) to encourage communication among basic research scientists working in related fields, 3) to promote the development and/or expansion of certain key areas in drug abu. research, and 4) to provide an interdisciplinary educational environment for students and faculty interested in various areas of drug abuse research. The philosophy of the Research Center is that drug abuse is a complex problem which needs to be studied on a variety of levels ranging from a drug's sub-cellular actions through its sociological impact. It is impossible for any single department, let alone an isolated individual, to possess the expertise to study drugs at all these levels. The Research Center has been to provide a formal structure for encouraging interaction between scientists and clinicians from several academic departments, all of whom are working in areas related to drug abuse. Current research includes: studies of drug self-administration in infra-human primates as well as man; studies of the sensitivity of current and former methadone dependent humans to alcohol and amphetamines; neurochemical studies of drugs of abuse; metabolism of drugs of abuse in animals and man.

MAINTENANCE, EXPANSION AND ANALYSIS OF THE DAEDAC DATA BASE

S.B. Sells, Texas Christian University, Inst. of Behavioral Research, *P.O. Box 29010a, T.C.U. Station, Fort Worth, Texas* 76129

The Drug Abuse Epidemiology Data Center (DAEDAC) is a research archive currently operated by the Institute of Behavioral Research (IBR) at Texas Christian University (TCU). Since its inception in November 1973, DAEDAC has been developed into an extensive and richly endowed data source for research and information on the epidemiologic and social science aspects of drug abuse in the United States. The DAEDAC maintains two types of files: the Original Data File and the Aggregate File. The Original Data File contains the largest single collection of coded raw data from original drug surveys, evaluation studies and drug abuse epidemiology studies. The Aggregate File is a computerized file of research literature containing bibliographic citations, summaries and data tables coded from research reports, studies and journal articles on drug abuse. The objectives of this contract are: 1. Preservation and maintenance of original drug abuse data files; 2. Organization and documentation of data files to facilitate secondary analysis; 3. Development and maintenance of a library of research reports of special interest to professionals and administrators working in the drug abuse field; 4. Development and maintenance of a computer file with retrieval software to provide bibliographies, statistical tables, and other relevant information on drug abuse problems addressed in the research literature; 5. Provision of data, analyses, bibliographies, special reports, and other information based on archive holdings to NIDA staff in response to specific research and technical questions; 6. To fully apprise NIDA about DAEDAC's operations and procedures; and 7. To provide for the transfer of the DAEDAC archive, including files, software, and documentation to any group or organization competitively selected by NIDA.

ADOLESCENT DRUG ABUSE ETIOLOGIES

P.M. Bentler, University of California, Los Angeles Campus, School of Letters & Science, Dept. of Psychology, *405 Hilgard Ave., Los Angeles, California* 90024 (P01 DA 01070-06)

The proposal describes the development of an integrated series of research projects aimed at understanding the social and psychological etiological bases of adolescent drug abuse. The research framework involves family background variables, interpersonal process and peer influence variables, situational variables, sociocultural variables, and other measurable factors such as attribution processes

that have been considered theoretically or shown empirically to be relevant to understanding the development of drug use patterns. Five specific research projects are conducted, with each project including numerous separate but related studies. Particular attention is paid to predictive, longitudinal research, causal modeling, and multimethod measurement.

Implementation of the coordinated research effort rests with the professional staff. In addition, consultants are utilized in research workshops organized to evaluate the relevance of new methodological techniques to drug abuse research and to produce state-of-the-art introductions and reviews of the methods. Two committees of individuals committed to understanding drug abuse, but not involved in the research effort itself, provide input to the research program; these are a university-based research advisory committee and a community-based advisory council.

ADOLESCENT DRUG USE IN THREE FAMILY CONTEXTS

B. Rosman, Philadelphia Child Guidance Clinic, *1700 Bainbridge St., Philadelphia, Pennsylvania* 19146 (R01 DA 01629-03)

The purpose of the proposed research is to test the relationship between drug abuse problems in adolescents and their family characteristics. Three hypotheses will be tested: (a) three specific patterns of drug use and abuse in adolescents emerge in three different family contexts; (b) self and parent concepts of the drug using youngsters are related to the different family patterns; (c) changes in family characteriestics effected by family treatment organized around the specific type of family dysfunction will be associated with symptom improvement; and with changes in self and parent concepts.

45 adolescents with drug related problems and their families will be studied; 15 of these will be youngsters who overdose with suicidal ideation, 15 who present as delinquents, where drug use is one among a number of behavior problems and 15 who are habituated users of amphetamines, barbiturates, and paint and glue sniffers. Family characteristics and organization will be assessed using interactional measures; parent and self concepts will be measured by questionnaires. The three groups will be compared on the measures prior to receiving family therapy to test the hypotheses relating family characteristics to pattern of drug use. Pre and post family therapy assessments will be compared to evaluate the relationship between changes in family organization and changes in symptom behavior, home and school adjustment, self and parent concepts.

SOCIAL FACTORS AND DRUG USE IN AN URBAN POPULATION

S.B. Sells, Texas Christian University, Inst. of Behavioral Research, *P.O. Box 29010a, T.C.U. Station, Fort Worth, Texas* 76129 (R01 DA 01765-02S1)

A major objective of the proposed research is to develop methods whereby the prevalence of drug use can be (a) accurately and economically estimated for specific drugs, population groups, and residential areas, (b) placed within a context of other health and social problems, and (c) related to social dimensions which characterize residential neighborhoods. The setting of this research in Dallas, Texas, a large triethnic city in the Southwest, is expected to favor the additional aims of gaining new understandings of the epidemiology of drug abuse and of developing prevalence estimates which are maximally useful in the planning of intervention programs.

Based on factor analytic and clustering techniques applied to 1970 Census data, sociodemographic factors will be defined for approximately 30 resideetial areas of the city, and will then be extended to the 1974-1978 time period on the basis of local survey and other intercensal data. The resulting sociodemographic measures, along with a large number of drug, health, and social indicators, by residential areas, will constitute the independent variables in the research.

Criterion variables will consist of direct estimates of the prevalence of prescribed use of psychotherapeutic drugs and the nonmedical use of various drugs, including alcohol and tobacco, by population groups of particular residential areas. These estimates will be based on a citywide school survey and a household sample survey, covering both adults and youth.

MONITORING THE HEALTH IMPACT OF PUBLIC POLICY DECISIONS ON ABORTION

W. Cates, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Abortion Surveillance Branch, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333

CDC has analyzed different national data bases to determine the effect of the increasing availability of legal abortion on trends in abortion-related deaths and hospitalizations in the United States. Moreover, we have designed specific projects to monitor the health impact of 2 recent policy issues: restricting public funds for abortion and requiring 'informed consent' provisions for women obtaining abortions.

SEROLOGICAL AND IMMUNOMORPHOLOGICAL STUDIES ON HEPATITIS TYPES A AND 'NON A-NON B'

A. Nowoslawski, National Inst. of Hygiene, Dept. of Immunopathology, *24 Chocimska St., 00791 Warsaw 36, Poland* (05-341-C)

The purpose of this project is to obtain data on the incidence of hepatitis type A and type 'non A-non B' and to determine the significance of these infections in the development of chronic liver disease and in the pathogenesis of chronic glomerulonephritis and periarteritis nodosa. Methods for serological and immunomorphological diagnosis of hepatitis A will be developed. These methods, together with those already available for identifying hepatitis B infection, will be used to identify 'non A-non B' cases.

JOINT PROGRAM FOR THE STUDY OF ABORTION/CDC

W. Cates, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Abortion Surveillance Branch, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333

CDC conducts the Joint Program for the Study of Abortion/CDC (JPSA/CDC), a multicenter prospective study of the early complications of legally induced abortion. Including reports of over 150,000 abortions between 1971 and 1978, JPSA/CDC represents the largest abortion study performed to date in the world. The series of publications from this work have advanced the potential for preventing abortion morbidity by documenting the safest possible abortion methods for different gestational ages. If new funding becomes available, data collection will continue through the competitive contract process.

EPIDEMIOLOGIC SURVEILLANCE OF ABORTION-RELATED MORTALITY

W. Cates, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Abortion Surveillance Branch, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333

CDC has been monitoring all deaths related to abortion since 1972. The number of deaths has declined from 89 in 1972 to 26 in 1976. Preliminary information for 1977 indicates a slight increase in the number of abortion-related deaths. CDC investigates each case both to identify risk factors and to ascertain preventable performance problems; it disseminates these findings through national meetings and publications.

IMMUNOCHEMICAL ANALYSIS OF PROTEINS AND POLYSACCHARIDES OF CRYPTOCOCCUS NEOFORMANS

E. Reiss, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Bureau of Lab., Mycology Division, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333 (CDC/BL/M-0013)

PROJECT DESCRIPTION: Currently, no well-defined skin test antigen for cryptococcosis is available to physicians and epidemiologists. Furthermore, the mechanism of cryptococcus neoformans pathogenicity is not clear. Studies are being carried out to fractionate subcellular components of the pathogen in order to purify and characterize a microsomal fraction capable of eliciting delayed cutaneous hypersensitivity. The antiphagocytic properties of the capsular polysaccharide and its effect on antibody formation by the host is also being investigated. The structure of the cryptococcal polysaccharide is being delineated as it relates to antigenicity. A skin test antigen will be supplied to a CDC epidemiologist for in vitro lymphocyte test of humans.

ST. LOUIS ENCEPHALITIS AND RELATED FLAVIVIRUS STUDIES

T.P. Monath, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Bureau of Lab., Vector Borne Diseases Division, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333 (CDC/BL/VBD-0106)

These studies are designed to evaluate the role of virus and host variation in determining the different geographic and ecologic patterns of St. Louis encephalitis and related flaviviruses. The natural variation of flaviviruses is being evaluated by analysis of genetic, pathobiologic, and immunologic factors. Geographically and ecologically representative virus strains are being evaluated with respct to intrinsic factors of virus structure, molecular biology, pathogenicity, vertebrate host specificity, and types of host immune responses. Substructural viral elements are analyzed by immunochemical methods. These studies will provide information to explain the absence of SLE epidemics in tropical America, the milder appearance of the disease in the far western U.S. and will elucidate the viral genetic factors which modulate virulence.

HOST-PARASITE RELATIONSHIPS, IN VITRO CULTIVATION OF PARASITIC ORGANISMS, AND IMPROVEMENTS IN IMMUNODIAGNOSIS OF PROTOZOA

G.S. Visvesvara, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, Bureau of Lab., Parasitology Division, *1600 Clifton Rd. N.E., Atlanta, Georgia* 30333 (CDC/BL/P-0006)

PROJECT DESCRIPTION: Protozoan diseases, such as amebiasis, giardiasis, amebic meningoencephalitis, malaria, and pneumocystis, cause a great deal of morbidity and, occasionally, mortality throughout the world. Many aspects of the epidemiology and host-parasite relationship of protozoan parasites need to be clarified. New methodology for the cultivation of parasitic protozoa is needed for the production of specific antigens for serodiagnosis. The specific diagnosis of these diseases needs to be improved. In vitro axenic and polyxenic cultivation and in vivo animal experiments to prepare antigens and to evaluate new diagnostic procedures are being done. The goal of these studies is to increase our understanding of parasitic diseases and improve techniques with which to better organize resources for their identification and control.

DISABILITY CONDITION IN THE WORKFORCE - PHASE II

J. Kennedy, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Surveillance Hazard Evaluations & Field Studies Division, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMO-G11-575)

The project will be carried out in FY'78 and FY'79 and use industrial classification of workers in studying their disabling conditions. The purpose of this project is to extend a previous analysis of disability data which did not contain industry of the worker as a coded variable. Utilizing linear model theory and techniques so derived, we propose to: 1) analyze the industrial classifications; 2) analyze the occupations of individuals identified with a primary or secondary disability condition thought to be occupationally related.

Using data compiled by the Social Security Administration, NIOSH would arrange an Interagency Agreement to obtain the needed information on computer tape. The data set of disabled workers would include age, race, sex, disabling conditions, occupation, time in occupation, and industry.

FETAL MORTALITY STUDY

J. Kennedy, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMO-W11-519)

The National Center for Health Statistics (NCHS) has planned to conduct a 1978 National Fetal Mortality Survey in conjunction with the 1978 National Natality Survey. NIOSH would form an agreement with NCHS to collect on the questionnaires occupational information on the parents, particularly the mother, in these surveys. (NIOSH would assure that NCHS adapts standard occupational questions such as those used by the Bureau of Census. The actual coding of the occupation and industry data would be carried out and conform to the classifications set forth by the Bureau of Census.) NCHS staff along with NIOSH staff would determine suitable analysis, plan, and write one or more reports utilizing the occupational data. NIOSH staff would consult on the contents of these reports. Also, detailed raw data tapes of this study will be provided to NIOSH for further analysis.

FY-78 ACCOMPLISHMENTS: Although the surveys are presently scheduled approximately one year later than originally planned, successful completion of critical efforts necessary in the operation of these surveys were made in 1978. NCHS has filled all of the fulltime staff positions for the surveys. OMB clearance was granted for the questionnaires and for the pretest of the surveys. Final questionnaires were prepared for printing.

It should also be noted that NCHS has elected to postpone the pretest surveys until January 1979 in order to allow optimal conditions for a favorable response rate.

IDENTIFICATION OF OCCUPATIONAL GROUPS AT HIGH RISK OF CANCER

J. Kennedy, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Surveillance Hazard Evaluation & Field Studies Division, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMO-C11-512)

Activities listed below are contracted out to the Johns Hopkins University, Dr. Irving I. Kessler, Principal Investigator, and have been carried out since June 1975.

The purpose of this project is to identify high-risk occupational groups in terms of incidence of certain rare cancer sites. The analysis would make it possible to identify potentially dangerous occupational exposures. The results obtained from two independent analyses will allow examination and re-analysis of most data sets in terms of morbidity (cancer) from dangerous occupations or industries newly identified.

From an existing data base containing lifetime occupational information on: a) 800 patients divided into 2 equal groups (persons with cancer of the urinary bladder and persons with other diseases -excluding cancer of any kind); b) a group of more than 1,800 patients (one-half with one of several neoplasms); and c) a group of 1,392 patients (one-half with Parkinson's Disease and the other half without this condition); high-risk occupational groups will be identified in the disease groups.

During FY 77, Dr. Kessler, Principal Investigator, presented some results on the bladder cancer patients to the Surveillance Branch and other interested persons in NIOSH. At the time of the presentation, improvements and refinements to the research by the addition of input from industrial hygienists were suggested that would allow NIOSH to gain the greatest benefits. A modification and extension of the contract has been proposed for incorporation into this project for FY 78 and FY 79.

FY 78 ACCOMPLISHMENTS: Project continuing as planned. Anticipate delays due to Principal Investigator changing his primary affiliation from Johns Hopkins to University of Maryland.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF PHOSPHATE WORKERS

T. Meinhardt, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C22-562)

NIOSH is conducting an epidemiologic study of the mortality patterns among phosphate (fertilizer) production workers. Interest in the chronic health effects associated with this industry developed because of three observed cases of lung cancer in phosphate production workers. All three men were reported to be non-smokers. The hypothesis of an association between lung cancer and phosphate exposure seems to be supported in studies by other federal agencies and the Florida State Department of Health, all of which have suggested an increased rate of lung cancer among the county populations surrounding the phosphate plants. This study involves a retrospective cohort study of workers' mortality patterns and industrial hygiene evaluations which will be used to characterize the working environment. To date, personnel information has been gathered and is being coded to produce working computer files. Also industrial hygiene reports have been drafted and are being finalized. Location of work experience is currently being coded on all former employees who have worked for companies in the study. This information will be used to limit the study to an appropriate cohort and expedite progress on the study.

INSULATING MATERIALS, LONG-TERM INHALATION EFFECTS - EPA

W. Moorman, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Biomedical & Behavioral Science, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VOO-E24-340)

Chronic biologic effects following long-term inhalation of fibrous glass used in insulating trades will be studied via the contractual route. Specific objectives include: 1) the evaluation of carcinogenic risk; 2) the fibrogenic potential; and 3) the character of pulmonary responses, both physiological and pathological (including deposition patterns). The results from this effort will be useful in evaluating the validity of the NIOSH proposed standard.

These objectives were identified as research gaps in the 1974 NIOSH-sponsored symposium (Occupational Exposure to Fibrous Glass - HEW Publication No. (NIOSH) 76-151) on fibrous glass and the 1977 NIOSH Criteria Document for Fibrous Glass. The increased usage, along with epidemiologic and experimental data, emphasizes the need for such a long-term investigation.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO ETHYLENE OXIDE - NCI

R. Rinsky, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C21-588)

Evidence exists indicating that ethylene oxide is a carcinogen and mutagen in animals. Industrial hygiene and mortality studies will be performed on a cohort of workers exposed to this agent. The mortality study will be conducted to determine whether or not an excess number of cancer deaths (or any other type of deaths) have occurred among deceased workers from the plant or plants being investigated. Detailed industrial hygiene studies will be conducted for the facilities included in the mortality study. Personal monitoring of workers' present exposure in selected job categories will be conducted at each facility. Attempts will be made to determine exposure levels in the past. Preliminary studies of manufacturing plants have been conducted.

One manufacturing plant has already been chosen for study; however, these workers also have exposure to the derivatives of ethylene oxide such as ethanolamine, ethylene glycol, etc. Definite plans have been made to obtain personnel records from this plant. Also, plants for conducting an in-depth industrial hygiene study have been established.

The search for another study cohort which has not experienced exposure to the derivatives of ethylene oxide is continuing. In the event a cohort like this is found, it too will be the subject of an in-depth mortality/industrial hygiene study.

The results of these studies will be used in the development of a recommended safe exposure standard.

STUDY OF NOISE/HEARING IN THE PAPERWORKING INDUSTRY

R. Tubbs, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Biomedical & Behavioral Science, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VOG-G22-364)

The purpose of this study is to critically examine the hearing and daily noise dose of workers in the paperworking industry (at the request of the United Paper workers International Union) and other industries when non-steady state noise is thought to exist. The hearing of several hundred paperworkers has been tested and recordings of daily noise exposure of a selected number of workers performing a variety of paperworking jobs have been obtained.

A critical analysis of both the audiometric and exposure data will be performed and correlated. Should the present sample size be insufficient, it will be expanded to additional plant(s).

Finally, plant tours of additional industries will be conducted in an effort to quantify the populations and types of jobs and industries where non-steady state noise exists.

INDUSTRIAL HYGIENE STUDY OF NEW AGENTS II - NCI

J. Oser, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C21-597)

Newly suspected hazardous agents are continually being identified in the industrial environment. This project is designed to obtain information about these agents and to determine the extent of industrial exposure and the feasibility of conducting epidemiological studies.

The industrial hygiene component of this study will be by contract. Epidemiological evaluations will be conducted inhouse.

The essentials of the study include literature search and review, industrial hygiene walk-through and monitoring and the assessment of employee records to determine possibility of mortality study.

Contract #210-76-0162 with Stanford Research Institute (September '76 to March '79) is in progress. This contract proposes to study four industrial agents. These include ethylene dibromide, ethylene oxide, toluene and zeolite. The first two of these agents, ethylene dibromide and ethylene oxide are complete. The remaining two, toluene and zeolite are scheduled for this FY.

ROOFING ASPHALT, PITCH AND UVL CARCINOGENESIS (NCI)

P. Niemeier, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Biomedical & Behavioral Science, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VOO-C24-399)

Increased risks of developing skin cancer and cancer at other sites, i.e., bladder, upper respiratory tract, stomach, leukemia, etc., have been demonstrated for those individuals working for 20 or more years in roofing operations (Hammond et al., 1976).

The purpose of this project is to assess the carcinogenic potential of condensed volatiles from roofing asphalts and coal tar pitch materials when collected from fumes generated at the respective application temperatures. C3H/HeJ and Swiss mice will be used to determine the response to long-term administration of the condensed volatiles through repeated topical skin applications. The phototoxic and/or cocarcinogenic effect of exposure to simulated sunlight (wave lengths greater than 290 nm) will be assessed in this investigation in one half of the experimental animals. Four materials will be used, including: a flat and a steep roofing asphalt, a routine and a 'low-burn' roofing coal tar pitch. All materials will be heated at and above their application temperatures used in the roofing operation. Analyses of the condensed volatile components will be made to estimate both polynuclear aromatic hydrocarbon and metals content. All work will be performed via the contractual route. The contract proposals have been received, evaluated and are currently in the negotiation stage. FY 79 efforts will involve contract monitoring and site visits.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF PCE WORKERS

D. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Surveillance Hazard Evaluations & Field Studies Division, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C21-547)

Perchloroethylene (PCE) is used extensively throughout the dry cleaning industry (300,000 workers). To date, the effects on humans of long-term low level exposure to PCE is unknown.

This study will assess the health effects of exposure to PCE by analysis of cause specific mortality among an identified group of dry cleaning workers. A cause of death for each individual in the cohort will be determined retrospectively and the observed deaths will be compared to those expected based on a standard, race, sex, and age specific population. Industrial hygiene surveys will be conducted by NIOSH to characterize worker exposure to PCE in the dry cleaning industry.

Union records are being used to identify dry cleaning workers who qualify for the study. Four labor unions have been selected and the personnel records of their members have been microfilmed. Much of the demographic data has been coded and vital status follow-up has begun.

2.0333,

MORTALITY STUDY OF PESTICIDE FORMULATORS/MANUFACTURERS

D. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C22-619)

Although pesticide formulators/manufacturers have been studied by numerous investigators, only minimal attention has been paid to chronic long-term effects. To date, there have been no reported retrospective mortality studies that have been completed on sufficiently large enough cohorts of workers, exposed to high levels of pesticides, to yeild definitive information. Published studies do suggest, however, that chronic or long latency disease may include cancer, kidney and liver disease, suicides, accidents, hypertension-related disease, and abnormalities of offspring. Any of these diseases may be attributable to a single pesticide or class of pesticides.

The nature of the formulating and manufacturing industry places these workers in a potentially highly exposed category. They traditionally manufacture, dilute, mix, and package a large variety of pesticides and diluents which change from season to season and from year to year depending on demand.

The primary purpose of ths project will be to determine if selected groups of pesticide manufacturers are experiencing excessive cause-specific mortality.

INDUSTRIAL HYGIENE STUDY OF PETROLEUM PRODUCTION - EPA

C. Cox, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Surveillance Hazard Evaluations & Field Studies Division, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-E22-584)

Petroleum refineries in the U.S. process crude oil into approximately 3 x 10 to the 6th power m3/day of refined products. By definition refinery activities start with crude oil storage and terminate with storage of the refined products. There are approximately 250 refineries in the U.S. employing about 100,000 production workers. Refineries range in size from 500 to over 64,000 m3/day, with the average refinery processing 6900 m3/day.

Over 300 different chemical compounds may be present in crude petroleum, with additional compounds being formed during the refining process. Since the health effect on refinery workers resulting from these chemical compounds has not been well defined, toxic and carcinogenic chemicals may be present in the working environment during the refinement of crude petroleum.

The purpose of the project is to identify and quantify worker exposure to potentially hazardous agents in refineries and to provide baseline data which may be used to assure safe and healthful working conditions in the petroleum refineries. Project objectives will be achieved by conducting an in-depth industrial hygiene characterization of worker environments in selected refineries, at selected unit operations, and/or within selected job classifications. A contract will be awarded in September, 1978, to accomplish this project.

PSYCHOLOGICAL EFFECTS OF CARBON DISULFIDE

B. Johnson, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Biomedical & Behavioral Science, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VOB-B21-306)

Carbon disulfide, a solvent used in viscose rayon manufacture, is known to cause neurological dysfunction and psychological disturbances in workers excessively exposed. The effects, however, of chronic exposure to low levels of CS2 at the existing Federal exposure limit have not been investigated. The purpose of this investigation is to examine the psychological state of workers chronically exposed to CS2. Specifically, as part of a biomedical investigation performed by DSHEFS, 300 workers (plus matched controls) will be given standard psychological tests to determine measures of anxiety, depression, and hostility; together with measures of psychological stress. In addition, psychometric tests of visual and aural function, reasoning ability, response time, coordination, and task time sharing will be administered to ascertain degree, if any, of function loss. Work histories and plant records will be used to derive exposure indices, which will then be used in correlational analyses with the psychological and behavioral data.

During FY-78 a worker population for study was identified in Tennessee, the study protocol was designed and submitted for Human Subjects Review Board approval, and testing equipment was assembled. During the first quarter of FY-79, testing of workers will be performed.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF PRINTING TRADES

M. Boeniger, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C22-560)

Published literature on the printing trades suggests that a significant number of health hazards exist. Workers are exposed to a variety of substances, i.e., carbon black, oil mist, polychlorinated biphenyls, polyvinyl chloride, carbon disulphide. A number of unusual health conditions observed in earlier studies have been suggested by researchers. These are cancers of the skin, lung, bronchial cavity, digestive system, and bladder. Other suspected diseases include increased heart disease, acro-osteolysis, and cirrhosis of the liver. detailed characterization, including industrial hygiene assessment of the industry and a retrospective study of the mortality patterns among selected specialists within the printing trades industry, is being conducted. The contractor, Mt. Sinai

Hospital, New York City, has performed walk-through industrial hygiene studies in selected printing establishments. Records from a printing union local have been collected and are being analyzed.

NIOSH is extending its study of the printing industry to the point of purchase segment of the screen printing trades. In-depth industrial hygiene characterization of this trade will be performed in the New York metropolitan area. All work in this latter study will be conducted by NIOSH industrial hygienists.

MORTALITY, MEDICAL AND INDUSTRIAL HYGIENE STUDY OF THE PAINTING INDUSTRY

D. Zaebst, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C22-559)

A pilot study conducted by the Mt.Sinai School of Medicine of over 1,000 members of the International Brotherhood of Painters and Allied Trades (IBPAT) under a NIOSH Contract demonstrated the existence of several significant health hazards in the painting industry. Anesthetic effects of the central nervous system were widespread and troublesome. The effects were especially evident among epoxy painters. Respiratory irritation as manifested by increased bronchitis, etc., was seen in sand blasters and metal painters. Chest x-ray changes such as pleural thickening or the occurrence of small rounded opacities were found to be especially evident among general painters, paint manufacturers, and sand blasters.

Therefore, in order to further delineate patterns of morbidity and mortality among applicators of surface coatings, a detailed characterization of industries employing these workers (excluding manufacture of paint) shall be conducted.

Fifteen to twenty sites in each of ten industries engaged in product finishing, and the IBPAT, have been contacted by NIOSH contractors. Walk-through surveys will be conducted in approximately five facilities in each of the ten product finishing industries; the feasibility of conducting mortality or morbidity studies of IBPAT records, and in-depth studies at one or more construction sites, will be selected for in-depth studies. These will include: (1) in-depth industrial hygiene surveys characterizing worker exposures found in the selected industries that employ painters, and/or (2) epidemiological studies and medical studies based on findings of the walk-through surveys and assessments of IBPAT records.

SURVEY OF CHRONIC DISEASE AMONG DEFINED U.S. WORKER POPULATIONS

V. Behrens, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMO-G11-607)

This project will develop the methodology to collect and analyze occupational, smoking and medical histories and morbidity information from industrial clinics and hospitals for defined worker populations in specific geographic areas. An interviewer-administered questionnaire, which is computer codable, to obtain occupational (places and dates of employment, job titles and descriptions, etc.) smoking and medical histories (for example family disease histories, drug and alcohol usage, chronic health problems) will be devised.

Mechanisms for taking interviews using this questionnaire in industrial clinics and hospitals will be devised, rated, and recommended. Methods will be developed to abstract, code and record on computer, morbidity and health effects information from records of admissions to industrial clinics and hospitals. Finally, two statistical methods will be documented (including computer programs) to analyze the interview and clinical data, the first method using demographic data (total population values for defined geographic areas and occupation and industry population estimates) to calculate incidence rates for groups of diseases and the second using a case-control approach to examine statistically specific diseases.

When completed a second project will be initiated to institute this methodology in an industrialized area of the U.S.

2.0342,

URANIUM MINES AND MILLS STUDIES

V. Archer, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMA-E22-637)

During the period 1950-1975, NIOSH collected data on about 20,000 uranium miners and mill workers. Further study and analysis of this data is expected to improve the exposure-response curve for lung cancer, to provide data on pulmonary disability and hair root changes, to determine if an altered sex ratio of offspring for uranium miners exists, and to determine if there is an excess of leukemia and cancer of the brain, pancreas, or bone in uranium miners.

Using data from Swedish and other mining groups, a dose-response curve has been constructed extending to quite low levels. This curve suggests that alpha radiation at very low dose rates induces 5 to 10 times as much cancer as equal amounts of radiation at higher dose rates. If this phenomenon is correct, then there are definite implications for setting lower standards, especially for radon daughters in uranium mining and plutonium in the nuclear power industry. Because of importance of the implications, verification or rejection of the present composite exposure-response curve is highly desirable. A retrospective mortality study on new cohort of approximately 3000 uranium miners having less than 12 WLM/year exposure and two control groups will be conducted to test this hypothesis.

2.0343,

INDUSTRIAL HYGIENE STUDY OF SOLAR ENERGY COMPONENT MANUFACTURE - EPA

M. Boeniger, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Surveillance Hazard Evaluations & Field Studies Division, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-E22-583)

A new technology which will be playing an increasing role in meeting this countries needed energy demands will be in the utilization of solar energy cells for direct conversion of solar light to electricity. While rapid technological developments are occurring in this field, the present view is that the silicon and cadmium sulfide type photovoltaic cells will dominate the future market. Though photovoltaic conversion of solar energy still plays a very minor role in the total energy supply it will probably make dramatic gains in the near future. For instance, at the close of 1975 approximately 10 Kw from terrestial applications was obtained from solar cells while in 1976 300 Kw are anticipated. Major declines in cost of these cells with moderate increases in efficiency are foreseen and will further their acceptance. Corresponding manpower demands would also be expected.

The production of the final solar collection panel is preceded by many refining steps. Potential health hazards exist, beginning with the initial mining and purification of cadmium and silica bearing ore, the growth and doping of the crystals with boron or phosgene, polishing the crystals with strong acids and caustics, to the installation of the crystals within collection panels. Employee exposures and environmental health aspects in all these refining processes should be evaluated while the industry is still in its infancy.

Establishment of practicable production guidelines for the safeguard of employees health and safety would allow this industry to develop without detrimental side effects.

CROSS-SECTIONAL INDUSTRIAL HYGIENE & MEDICAL SURVEY OF NON-TEXTILE COTTON

R. Piccirillo, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKH-R22-208)

Byssinosis is a well established hazard in the cotton industry. Previous studies have focused on the textile industry. Available dose-response data, the basis for establishing safe exposure levels, are based entirely on studies of byssinosis in the processing phases of the primary textile industry. In parts of the cotton industry, the workers are exposed to dust that is qualitatively different from that in the processing phase of the textile industry. It is necessary to characterize the dose-response relationship in these industries.

Workers involved in the manufacture of cotton pads for mattresses and cotton batting, cottonseed oil mill workers, waste utilization, cotton warehouses and cotton classification offices, are five groups who are exposed to dust which may be different from primary textile dust. Groups of 300-400 workers from each segment will be studied. The biologic response to cotton dust will be characterized by medical and environmental testing.

Contract for the gin and warehouse segment of the study has been awarded. Final clearance was re-

ceived for the in-house phase of the industry and approximately 1/4 of the sample has been studied.

2.0345,

IMMUNOGENETICS OF BERYLLIUM DISEASE IN HUMANS

S. Olenchock, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKC-C21-180)

The continuation of this project is designed to survey the HL-A antigenic determinants on cells from patients with beryllium disease. These results will be compared with HI-A antigenic determinants on cells from patients with sarcoidosis in order to investigate possible genetic similarities to dissimilarities between individuals with either disease. Individals in the following populations will be studied; patients with chronic beryllium disease, beryllium workers without disease, patients with sarcoidosis, and appropriate geographical controls with no pulmonary disease.

A questionnaire will be administered to volunteer subjects and whole blood will be obtained by venipuncture and the cells analyzed for HL-A determinants and blood grouping. Split blood specimens from appropriate test and control sample populations will be utilized to measure MIF production by leukocytes for evaluation of specific hypersensitivity to beryllium compounds. In addition, serum will be examined for total immunoglobulin and C4/4 levels, and the following traits: alpha-1-antitrypsin levels, anti-nuclear antibody, rheumatoid factor, and immunosuppressive/regulatory activity.

2.0346,

INDUSTRIAL HYGIENE STUDY OF GRAIN DUST EXPOSURE

T. Thedell, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKP-R21-206)

The objective of the ongoing study has been to evaluate the presence and extent of health hazards associated with occupational exposure to grain dust and other potential etiological agents of respiratory diseases to which workers in the grain elevator industry are exposed.

Major accomplishments of this project to date include the sucessful completion of walk-through surveys and in-depth field surveys of port terminal grain elevators located in the upper Midwest as well as the development of new sampling methodology from collecting large quantities of respirable grain dust for laboratory analysis.

The major objective of the final year of study is to critically test a null hypothesis that randomly selected port terminal grain elevators from seven identified geographical stratums do not statistically differ in respirable and total grain dust mean concentrations from the previous Duluth port terminal data. Other objectives will be to investigate dose-response relationships of grain dust exposures, support LIB investigations of grain dusts, compare country grain elevator and evaluate new equipment and methods.

2.0347,

DISEASE PREVALENCE AND HEALTH HAZARDS OF GRAIN HANDLERS

P. Major, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKC-R22-164)

The opportunities for potentially hazardous exposures to grain dusts exist at many occupational situations. These include loading/ unloading, storage processing, and shipping of various grains and grain products. During the majority of these processes, dusts are generated which have the size and aerodynamics capable of reaching both the upper and lower respiratory tracts. Previous research studies have demonstrated an excessive prevalence of chronic nonspecific lung diseases and related health problems in the grain handling industry. However, owing to great diversity in scientific design and approach which has been used by various investigators in studying the respiratory symptoms of grain handlers, little data which is standardized and therefore comparable exists. Also, responsible environmental assessment of the industry is absent.

It is the purpose of this project to address the medical aspects and other consequences of occupational exposure to grain dusts and to determine what effects and the extent of these effects such exposure has on the labor force in this industry. The project is divided into three approaches: Clinical/Epidemiological - by contract; laboratory, in vitro analysis - in house; and environmental assessment - in house.

Past accomplishments of this project include completion of Phase and most of Phase II for the Grain Handlers Contract # 210-76-0175; award and partial completion of service contract #210-77-0150; completion of co-sponsorship of an 'International Symposium on Grain Dust and Health--Canada (11/77) plus four resulting publications and draft of symposium proceedings to be published in 1/79.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health $46,438

2.0348,

MORTALITY OF COAL MINERS IN THE UNITED STATES

C. Ortmeyer, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKL-R22-182)

This project is aimed mainly at determining age-standardized death rates of coal miners for all deaths, and for deaths from specified causes, principally pneumoconiosis, airway obstructive diseases and malignant neoplasms of the respiratory and digestive systems. Data which can be obtained about disabilities of coal miners determined by uniform medical criteria will also be used to determine age-standardized prevalences of disabilities determined to be serious enough to restrict employment. These death rates and disability prevalences will be determined for coal miners with varying kinds and durations of underground mining, and with varying categories and stages of coalworkers' pneumoconiosis (CWP). Three study groups of coal miners are now being followed for mortality: (a) an Appalachian bituminous coal miner employed when examined in 1963-65 and 1180 miners on the UMWA rosters of nonworking members when examined during the same period; (b) a study group of 3700 applicants for compensation in 1965-70 under a W.Va. state program of compensation for coal-dust-related disability; (c) a nationwide study group of about 12000 miners selected to be regionally representative of both bituminous and anthracite underground and surface miners examined during the period 1969-72.

A second purpose is to identify, measure and reduce ambiguities, biases and other nonsampling errors in estimates of death rates and of 'excesses' or 'deficits' in these rates relative to 'standard' rates. Nonsampling errors arise mainly from (a) lack of data, especially about 'standard' populations, on non-occupational factors elevate death rates, (b) gaps of up to 20-30 years in work-history data on study groups, and (c) inadequate reporting of chronic cardiopulmonary diseases on death certificates.

MORTALITY, MORBIDITY AND INDUSTRIAL HYGIENE STUDY OF BRAKE LINING WORKERS

S. Leffingwell, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C22-618)

The NIOSH recommended standard for asbestos exposure of 2.0 fibers longer than 5 microns per cubic centimeter of air was established with the recognition that: 1) health data was not available for exposures to low levels, and 2) definitive information on the biological response to different size fibers was not available.

Industrial hygiene surveys have been conducted in six automobile facilities by the Industrial Hygiene Section. Optical counting and electron-microscopic analyses are being performed in order to characterize the nature of the exposures occurring in these types of operations.

A contract has been let to the Environmental Sciences Laboratory, Mt. Sinai School of Medicine, to evaluate health effects of exposure to asbestos-containing dusts in brake-lining maintenance and repair. The contract consists of two evaluations: (1) a feasibility study, to locate a cohort of brake lining repair and maintenance workers - with sufficient latency to conduct a retrospective mortality study of these workers; and (2) a cross-sectional medical survey, to define the current health status of a representative cross-section of workers occupationally exposed to brake lining dusts. In conjunction with the cross-sectional medical study, NIOSH will undertake industrial hygiene assessments at a representative sample of work establishments from which the study participants have been drawn. Although the cross-sectional medical survey final report is due October 30, 1978, it is apparent that the report will not be finished until the second quarter of FY'79. Industrial hygiene assessment will be performed following receipt of work establishments from which participants were drawn.

The contractor has promised the final report on the mortality feasibility study to NIOSH by 11/1/78.

PILOT DEMONSTRATION PROJECT FOR WORKER NOTIFICATION, CONSULTATION AND MEDICAL FOLLOW-UP

J. Salg, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Surveillance Hazard Evaluations & Field Studies Division, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMO-C11-537)

For the most part, workers exposed to toxic substances are unaware of the existence of hazards and potential acute or chronic disease outcomes. Although most authorities agree about the principle of the worker's right to know, there is a gap in providing meaningful and timely information coupled with provisions for medical surveillance and counselling. The purpose of this project is to take a small group of workers who have been exposed to one or more of the regulated carcinogens, and develop protocols for follow-up, medical surveillance and counselling and to identify the kinds of information required for adequate surveillance and monitoring as a pilot study - specifically, those workers whose medical records were sent to NIOSH because they had been exposed to a regulated carcinogen and have terminated employment from a company covered by Federal regulations, Title 29, Chapter XVII, Section 1910-10, Subpart G.

This demonstration project could serve as a model for other large groups of workers who may, in the future, be placed under medical surveillance. Cooperation with NCI's cancer information service will be sought as regards the counselling and recommendation for medical screening. Also, an attempt will be made to obtain work history data on the group of workers under study.

FY-78 ACCOMPLISHMENTS: Follow-up activities have been initiated and will conclude by the end of FY-78. Accompanying file development activities (coding, data entry, etc.) will also be completed.

2.0351,

METHYL CHLORIDE/DRUG INTERACTIONS ON PERFORMANCE

V. Putz, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Biomedical & Behavioral Science, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VOB-B24-318)

This project represents the completion of human laboratory inhalation investigations which have focused

on the potential interactive effects on behavioral performance and neurologic function of an industrial solvent, methyl chloride, a common prescription drug (Valium), and twonon-prescription drugs, ethanol and caffeine. The intent of the project was to determine by developing dose-effect relationships the precise point at which the solvent in combination with each drug begins to produce changes in functional capacity. Methyl chloride was found in a NIOSH contract study (CDC-99-74-20) to impair workers' performance of tests involving cognitive time-sharing and also increased arm tremor. Valium is the most common prescription drug in current use (18 million prescriptions per year), while ethanol and caffeine are both common drugs having known central nervous system effects, but for which no information exists regarding possible interactions with methyl chloride (MC).

Activities during FY-77 and FY-78 consisted of completing the testing on the interactive effects of MC with Valium and MC with ethanol on human behavioral performance (signal detection, compensatory tracking, vigilance). Early findings from the blood and breath tests revealed large variations in individual uptake levels, which indicated major differences in human sensitivity to the solvent, methyl chloride. As a result of this observation, additional subjects were added to all phases of the investigation in order to determine the extent of distribution and behavioral impairments of those individuals who appear to be highly sensitive to methyl chloride. During FY-79 similar testing will be completed for MC/caffeine and the results from all three studies analyzed and prepared as a NIOSH report.

2.0352,
DEVELOPMENT OF EMPLOYEE-DERIVED EXPOSURE DATA

D. Sundin, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Surveillance Hazard Evaluations & Field Studies Division, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMO-G11-535)

The nationwide surveillance of occupational health hazards cannot proceed without effective and continuing contact with those directly affected - the workers. The employee is usually the first person to register awareness about the substances found in the workplace, and the first affected adversely if hazardous substances are improperly used. The employee is frequently uninformed as to the possible deleterious health effects of occupational exposures and usually unaware of potential sources of information and assistance.

Major repositories of data on employee complaints relating to occupational health hazards have been identified and analyzed for completeness and utility as early indicators of potential problems. A generalized process-efficient computer system to accept and display incoming data will be used to accumulate incoming information. As additional sources of data are identified and annexed, a bi-monthly or more frequent bulletin summarizing important new information will be published and disseminated to NIOSH and other researchers.

CANCER SURVEILLANCE OF OCCUPATIONAL COHORTS IN A WESTERN SMSA - NCI

R. Spirtas U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMO-C11-530)

This project proposes the examination of cancer incidence patterns among selected occupational cohorts in the greater San Francisco-Oakland SMSA. Numerouc unions and collective bargaining organizations maintain data on constituent members. Given existing data on known and suspected carcinogenic hazards present in the environment of these cohorts, the existence and applicability of union data facilitates the study of the occupational cohorts for unusual cancer incidence. Linkage of data such as this with data on cancer incidence in geopolitically defined populations provides direct comparison of cancer risks for selected occupatonal groups. The results of such efforts will assist industrywide studies in identifying groups at risk and thus encourage finer characterization of the occupational environment. These activities will benefit NIOSH programs in criteria document development and OSHA's program of standard setting. This particular project also explores the methodologic and technical problems associated with population-based cancer surveillance. The nature of the study necessitates a cooperative effort between the SEER participant in the Bay Area and NIOSH. A contract will be developed for basic data collection, update, edit, and preliminary analysis.

FY-78 ACCOMPLISHMENTS: Contract awarded. Initial visit to contractor made to discuss scope of work.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health $9,500

2.0354,
MORTALITY, MEDICAL AND REPRODUCTIVE STUDY OF ESTROGEN WORKERS

S. Tanaka, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-W21-605)

Synthetic estrogens are a group of synthetic hormones having serious potential effects on exposed workers. It has been documented that women taking oral contraceptives have an increased risk of thromboembolism, cerebral vascular disease, and myocardial infarction. A NIOSH Hazard Evaluation study which was carried out in an oral contraceptive plant indicated that problems are occurring in both males and females. These problems include gynecomastia and menstrual changes. It has also been noted that estrogens may be carcinogenic (e.g., DES is a transplacental carcinogen).

A cross-sectional medical/environmental study is proposed to investigate health problems occurring as a result of exposure to synthetic estrogens and to attempt to determine a safe level of exposure to these agents. The feasibility of a mortality study of workers occupationally exposed to products containing estrogens will be assessed. The study will be designed to determine if an excess number of carcinoma deaths have occurred in exposed workers.

Concern for an excess of miscarriages and birth defects related to employment at a pharmaceutical laboratory in Radnor, Pennsylvania, resulted in the request for a health hazard evaluation. Data provided by company officials indicate an unsuccessful pregnancy rate of 25.0% (8/31) for Research and Development personnel as compared to 10.8% (4/37) for the administrative personnel. Because this twofold risk is based on small numbers, the population of female workers needs to be further assessed to determine if a more complete data set will still result in the continued observation of an excessive risk.

2.0355,
MORTALITY, MEDICAL, AND REPRODUCTIVE STUDY OF LEAD WORKERS

S. Leffingwell, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C21-553)

Mortality Study of Lead Workers: Lead phosphate administered subcutaneously to rats has resulted in the induction of renal tumors. Renal tumors in rats have also been induced by lead acetate-containing diet. Lead oxide appears to act synergistically with benzo(a)pyrene in pulmonary tumorigenesis in Syrian hamsters, since lead is reportedly cumulative in the lung. Workers in lead smelters and battery plants may breathe or ingest lead as a result of poor work hygiene practices. Possible carcinogenic or co-carcinogenic effect deserves examination. Although the authors of a study concerning carcinogenesis among lead battery plant workers concluded that their results do not support a specific cancer risk, the data indicate that such a risk may be present. In order to further assess the possible excess cancer risk to lead exposure, a further retrospective cohort study is planned on workers exposed to lead and its compounds. A contract for establishing a master file and doing follow-up was given to Westat, Inc. The cohort has been identified and follow-up will be started soon.

Reproductive Studies: Since as early as the mid 1800s, the effects of lead exposure on human reproduction have been observed. In 1860, Constantin Paul collected case histories on the reproductive effects of lead through both male and female exposures. These effects included spontaneous abortions, stillbirths and infant death. Others have observed adverse reproductive effects in both wives of male lead workers and in women workers who have had exposure to lead. Recently, Lancranjan et al. (1975), in a study of 150 male lead battery plant workers, found that those in groups strongly affected by lead exposure had 'decreased fertility due to anthenospermia (reduced viability of sperm), hypospermia or oligospermia (both denote reduced numbers), or teratospermia (malformed), frequently associated.'

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health $95,000

2.0356,
CROSS-SECTIONAL EPIDEMIC AND INDUSTRIAL STUDY OF NEW AND EX-MINERS

J. Hankinson, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKH-R22-163)

This project is designed to answer the basic question: 'Are those miners who have already left the coal mining industry different from those who remain?' This question will be answered by investigating 'new miners' (those miners who work only for a few years and quit) and 'ex-miners' (those miners who worked for many years and quit). The ex-miners will be investigated by comparing data collected in the first and second round, to determine if they actually left the industry. Data from those who left will be compared with a matched group who remained. This will require no new data collection.

The overall purpose of the 'new miner' study is to determine if new miners develop acute changes in their lung function with dust exposure. The 'new miner' study will be divided into two phases. Phase I will consist of a detailed analysis of those miners who participated in the third round of the National Coal Study with less than 18 months of employment. These miners will be compared to a normal nonminer control group and a group of miners with more than 5 years exposure to coal mine dust.

Phase II of the 'new miner' study will consist of the repeat examination of approximately 100 miners with less than 1 year of employment. Their initial examinations will be conducted before and after a work shift. Follow-up examinations will be conducted at 6 months intervals for approximately 2 years.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health $153,725

2.0357,
MORTALITY OF DIESEL ENGINE MECHANICS

J. Costello, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKL-R22-228)

A few years ago a suggestion was made to introduce diesel powered equipment into underground coal mines to replace electrically operated equipment. Labor unions expressed concern about this in terms of both health and safety. NIOSH held a conference in September, 1977, to determine what was known about health effects of diesel exhaust. One recommendation of this conference was for NIOSH to look at a large population of workers who had been exposed to diesel exhaust in confined spaces for an extended period of time.

Diesel engines have been found to emit polynuclear aromatic hydrocarbons. Among these emitted polynuclear aromatic hydrocarbons are found benzo(a)pyrene(BaP) and benz(a)anthracene(BaA) which are known to be carcinogenic. Work by Carnow and others suggests that an increase of 1 mg/m3 BaP in urban pollution is associated with a 5% increase in lung cancer death rate. Battigelli and

others in 1963 looked at 210 workmen exposed to diesel exhaust in railroad engine houses and found that there was no significant difference in pulmonary function between these workers and a control group. However, the maximum latent period was 15 years with an average of 10 year exposure and the study group was small.

Railroads began dieselization in earnest after the Second World War and by 1953 were well on the way toward complete dieselization. We now have a maximum latent period of 24 plus years which should be long encugh to show evidence of lung cancer, if it exists, in these workers. This project will look at mortality patterns of a large group of workers in railroad diesel engine repair shops (and other diesel repair shops) where it is common practice for engines to be left running for adjustments. Particularly in inclement weather the shop doors are closed and inadequate ventilation may result. We will pick a sample of the larger shops in the eastern United States for this project.

2.0358,

MORBIDITY, MORTALITY AND INDUSTRIAL HYGIENE STUDY OF CEMENT WORKERS

A. Engelberg, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKH-R22-193)

For at least 40 years there have been studies performed to detect evidence of lung disease in Portland cement workers. The most recent epidemiologic study completed in Yugoslavia indicates that cement workers show significant increases in pulmonary symptoms and decreases in pulmonary functions related to chronic obstructive pulmonary disease, as compared to controls.

It is not known whether the results of the Yugoslavian study can be applied to cement workers in the United States. It is possible that the work environment in American cement plants is different enough to produce different results in a similar study.

Workers in the cement industry will be examined for evidence of both obstructive and restrictive (fibrotic) lung disease. Furthermore, personal dust sampling will be done at the study sites to develop 'dose-response' curves to the dust generated at the cement plants.

Results will also be compared to the results of 'Blue Collar' control worker survey soon to be initiated by NIOSH.

During FY 78, in consultation with union and industry, the study protocol was written. It received favorable peer review and was accepted by SPRG. Twenty-nine cement plants were selected as possible study sites, and are presently being visited to determine their suitability. Approximately 19 of these sites will actually be selected for study. Furthermore, a pilot study of dust level variability is being conducted to give insight into the amount of personal sampling that will need to be done in the industry-wide study.

MORBIDITY & INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO SOX, H2O4, NOX, NO3 - EPA

J. Gamble, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKL-E21-170)

The purpose of this study is to develop dose-response relations of both an acute and chronic nature for the various species of sulfur and nitrogen compounds in support of health standards development.

The two essential interdependent parts of this study are the measurement of dose and of response. A measure of environmental dose will be obtained by personal sampling for the compounds under investigation. Measurement of worker response include a questionnaire on demographic variables and respiratory symptoms, chest x-rays, and pulmonary function. A sample of the workers will be tested before and after work for changes in pulmonary function. Environmental measures will be taken concurrently. Levels of exposure that produce chronic effects will be estimated from total work history and environmental sampling at the time of the medical survey.

PAST ACCOMPLISHMENTS: Data collected has been completed for Dieselized Salt Mines (NO2), and Battery manufacturing plants (H2SO4).

SCAFFOLDS

J. Cavender, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Safety Research, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VLB-S31-838)

OSHA has identified scaffolding accidents as a category requiring special emphasis.

The purpose of this project is to provide continuity between NIOSH and OSHA on the effort to investigate injuries and determine causal factors of accidents involving scaffolds.

The Bureau of Labor Statistics, OSHA and NIOSH have been actively working on this problem through the use of BLS's Supplemental Data System. This system is in the initial stages of implementation and when fully implemented should provide detailed information on scaffolding accidents.

An interagency agreement with the National Bureau of Standards was initiated in May 1978 to provide detailed data on scaffolding accidents and injuries.

SAFETY INTELLIGENCE

J. Cavender, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Divison of Safety Research, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VLB-S11-849)

Safety Intelligence connotes the total process of gathering and organizing current occupational accident data for use in establishing priorities and directing the research efforts of the Division of Safety Research. Numerous data sources currently exist in other government agencies and the private sector that are continually monitored by the Safety Surveillance Branch in an effort to maintain the lastest po l of safety statistics for timely and efficient access.

In addition to the data collection, specific projects will be conducted using this data. One effort is aimed at identifying and isolating the industries and occupations that exhibit unusually high risk for injury, both in frequency and severity. Unscheduled, but periodic analysis sheets will be produced indicating the status of the industrial accident experience in as much detail as possible. Finally, a large quantity of first reports of injury will be taped to create a new original data source in extreme detail.

MORTALITY STUDY OF CRUSHED STONE WORKERS - NCI

J. Costello, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKL-C21-194)

As a result of researchers finding asbestos fibers in crushed rock being quarried in Maryland, negotiations were started and are continuing with the National Crushed Stone Associated to arrange for NIOSH to do national mortality study of workers in the crushed stone industry. Emphasis will be placed on causes of death related to cancer and pulmonary diseases.

As an integral part of this study, the Environmental Investigations Branch will examine and chracterize the rock that is being quarried. There are four basic types of rock being quarried and each type will be covered by our sample.

A draft protocol has been written and is under consideration by the National Crushed Stone Association.

2.0363,

MORTALITY, MORBIDITY, AND INDUSTRIAL HYGIENE STUDY OF OIL SHALE WORKERS - EPA

J. Costello, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKL-E22-189)

The purpose of this project is to determine the health effects, if any, of occupational exposure to shale oil. The study cohort is made up of a total of 429 men who worked at Anvil Points Oil Shale Retort and 15 men who worked at the Union Oil Retort in Colorado in the 1950's and 1960's. The project will consist of a mortality study (in-house) and morbidity study (outside contract). The mortality study will compare the mortality patterns among the male, caucasian, shale oil workers cohort with the mortality patterns of U.S. white males. Comparisons will also be made between those in the study group with high and low exposure to shale oil. The morbidity study will compare the morbidity patterns among the male, caucasian, shale oil worker cohort with the morbidity patterns of a matched control group from the Colorado Plateau (age, race, smoking, skin complexion, years on the Colorado Plateau, and time spent in outdoor activities). High and low shale oil exposure groups would be compared. Attempts to develop exposure indicies in both the mortality and morbidity studies will be made.

Representatives of EIB will continue to work with representatives of the USSR on the health effects of oil shale development. Contact will be made with individuals knowledgeable in oil shale technology and involved in industrial hygiene studies related to oil shale processing.

PATHOGENESIS OF ALLERGIC PULMONARY ASPERGILLOSIS

R.G. Slavin, St. Louis University, School of Medicine, Dept. of Internal Medicine, *1402 S. Grand Blvd., St. Louis, Missouri* 63104 (R01 OH 00398-06)

The first objective is to establish an animal model of allergic aspergillosis in non-human primates. Monkeys are sensitized with A. fumigatus to produce precipitating antibody. Human serum rich in IgE antibody to A. fumigatus is infused and the animals challenged with A. fumigatus aerosol. Changes in lung tissue are determined by light microscopy, immunofluorescence and electron microscopic examination of serially obtained open lung and transbronchial biopsied tissue. Bronchial lavage is performed and lavage fluid and cells evaluated for immunoglobulin and protein content, enzyme activity and evidence of cell mediated immunity. The same sensitization will be done in the monkey skin with serial biopsies. The second major objective is to continue studies on the epidemiology of allergic aspergillosis. In order to determine whether the increased incidence of this disease in Great Britian is due to differences in the atmospheric burden of A. fumigatus, air sampling in St. Louis will be carried out with an Andersen sampler and compared to Great Britain. Individuals with a particularly heavy exposure to A. fumigatus, namely organic farmers, will be evaluated for sensitivity to A. fumigatus by skin testing and precipitin testing.

NEUROTOXICITY AND TERATOLOGY OF INDUSTRIAL CHEMICALS

P.S. Spencer, Yeshiva University, Bronx Campus, Albert Einstein School of Medicine, Dept. of Neurosciences, *1300 Morris Park Ave., Bronx, New York* 10461 (R01 OH 00535-05)

This project is designed to study: 1) the mechanism of nervous system degeneration following exposure to neurotoxic chemicals used in industry, 2) the capacity for these chemicals to damage the developing nervous system, and 3) to design methods to screen chemicals for neurotoxic properties for the purposes of determining safe exposure levels and 4) to detect early nervous system damage in individuals occupationally exposed to neurotoxic chemicals.

Planned studies will continue to utilize correlated morphological and biochemical tools to dissect the mechanism of nerve fiber degeneration induced by acrylamide and solvents. Morphological studies will be initiated to study the response of the fetal nervous system to maternal exposure to these chemicals. Finally, the modified Optacon R, simple device for the assessment of decrements in palmar sensation, will continue to be developed and tested for its ability to detect sub-clinical occupational neuropathy.

THE ROLE OF ATOPY IN OCCUPATIONAL SKIN DISEASE

E. Shumes, University of South Carolina, College of Public Health & Associated Health Programs, *Columbia, South Carolina* 29208 (R01 OH 00954-01)

The objectives of this grant concern two areas. Regarding the role of atopy in occupational dermatitis the objectives are as follows: To demonstrate the incidence of atopy among the closed cases of Workmen's compensation in the State of South Carolina for the fiscal year July I, I976 to June 30, I977; To determine the incidence of atopy among the parents and family of the closed cases; To demonstrate the level to which employers are aware of the existence of atopy at the time of hiring employees in those plants in which a closed case of Workmen's compensation involving skin disease occurred.

Regarding the delivery of effective dermatologic intervention at the time of the active case of occupational dermatitis, the objectives are as follows: To identify contributing factors such as nature of in plant irritants or allergens, degree of personal protection used, and work practice routine involved by those employees who represented closed cases of Workmen's compensations attributed to skin disease; to determine the interval between development of the occupational skin disease and referral to trained personnel; To determine the level of medical and/or dermatologic training ultimately involved in the case; To develop a measure of credibility between information gleaned from the employees representing the closed cases themselves and the employers of the closed cases; To determine the ultimate disposition of the closed cases with respect to continuance, transferral, or termination at the place of employment.

LEAD EXPOSURE - ELECTROPHYSIOLOGIC/ PSYCHOLOGIC EFFECTS

R.G. Feldman, University Hospital Inc., *75 E. Newton St., Boston, Massachusetts* 02118 (R01 OH 00984-01)

The objective of the proposed research is to identify the most sensitive, specific, and reproducible screening methods for detecting disturbed central and peripheral nervous system function in workers exposed to lead. Earlier studies of lead neuropathy have suffered from methodological inconsistencies and inconclusive results. The proposed study will be a prospective evaluation of cohorts of 40 lead-exposed workers and 40 unexposed controls in which subjects will be tested three times over a three-year period. A 30% sample of subjects will be retested immediately after each of the three testing sessions to assess reproducibility of nerve conduction testing. The following data will be collected from each participant in the study: 1) work and medical history and demographic information; 2) motor and sensory nerve conduction evaluation of ulnar, peroneal, and sural nerves; 3) clinical neurologic examination; 4) psychologic measures of memory, intelligence, and dexterity; 5) blood lead and zinc protoporphyrin levels (collected bi-monthly).

Upon completion of the study, we will be able to recommend a standard methodology for evaluating neurologic effects of lead, and of other neurotoxins in occupational settings. Not only would such a protocol improve the comparability of studies performed by different investigators, but its systematized implementation by trained technicians would facilitate subsequent studies.

Furthermore, more precise dose-response relationships between neurotoxin exposure levels and neurologic effects could be developed and then used to establish permissable exposure levels in the workplace. Since many new chemicals will be introduced into industry in the future, the availability of this method and its criteria would greatly facilitate the evaluation of exposed workers.

2.0368,

MORTALITY EXPERIENCE OF WORKERS EXPOSED TO HALOETHERS

B.S. Pasternack, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016 (R01 OH 00932-01)

The primary purpose of this study is to examine the respiratory cancer mortality experience of workers in the chemical industry who have been exposed to chloromethyl methyl ether (CMME). This will be accomplished by updating the mortality experience for the period 1973-1977 among workers in the six firms previously included in our epidemiologic study of occupational exposure to CMME. In addition, all exposed and nonexposed production workers in a seventh firm (plant on the West Coast) will be included in our retrospective cohort for complete mortality follow-up from the year in which CMME operations first began, 1955, through the end of 1977. Respiratory cancer and other mortality experience of the CMME-exposed workers will be characterized according to duration and intensity of CMME exposure; the temporal patterns of respiratory cancer mortality, including estimation of the induction-latency period, will also be examined.

Ascertainment of deaths among separated employees will be based on the searching service of the Social Security Administration. Those not indicated as dead by the Social Security Administration will be traced further for vital status ascertainment by utilization of other resources including the Internal Revenue Service, Post Offices, State Motor Vehicle Bureaus and Union records. Death certificates will be located and obtained; diagnostic confirmations will also be obtained from appropriate physicians, autopsy records, and/or hospitals when any form of cancer is listed as a cause.

2.0369,

MORTALITY, MEDICAL, AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO WOOD PRESERVATIVES

S. Tanaka, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C21-654)

Wood preservatives are bactericidal, fungicidal, and insecticidal groups of chemicals used to preserve wood against rotting, termite infestation, etc. Examples are arsenicals, creosote, pentachlorophenol, chlorodiphenyls, chlorinated naphthalenes, dinitrophenol, thiuram, copper compounds, and alkyl mercury compounds. These chemicals are toxic to humans and will cause various health effects on exposed workers.

This program plan proposes a cross-sectional medical and industrial hygiene study on workers employed in the manufacture and use of wood preserving chemicals. Since diversified kinds of chemicals are involved, the first phase of the study will be devoted to determine the type and volume of chemicals manufactured or used, and the size of worker population exposed. On the basis of information collected in the walk-through surveys, a plan of study will be developed as to the type of population to be studied and to the methodology.

Currently, the Stewart-Todd Associates of Wayne, Pennsylvania, is about to conduct a number of walk-through surveys under a NIOSH contract on 'Wood Preservatives, Flame Retardants and Acrylates' (TOX-TIPS, September 1979, 40-29). The medical study portion will join this ongoing program to save time and cost and will conduct a cross-sectional medical study of selected groups of workers. A mortality study may also be considered if a suitable cohort is found during the walk-through surveys.

2.0370,

MORTALITY STUDY OF INCREASED BRAIN TUMOR INCIDENCE IN TEXAS CITY, TEXAS

S. Leffingwell, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C22-653)

In response to a complaint of alleged excessive brain tumors among employees at the Union Carbide Company of Texas City, Texas, the Houston South Area Office of OSHA launched an investigation in November of 1978. After a careful inquiry, OSHA requested technical assistance from NIOSH in evaluating the problem.

Preliminary data, supplied with aid of the company, local unions, and local physicians and surgeons, show ten cases in which death certificates indicated brain tumor as cause of death. One additional living employee was found to have a brain tumor. The cell types were predominantly glioma or glioblastoma multiforme with one 'meningioma, angioblastic (sarcoma)'. The workforce at the plant presently numbers 2500. Between 7.5 and 10 thousand workers have worked in the plant between 1941, when the plant began operation, and the present.

Present plans call for additional case-finding, case confirmation by pathological review of tissues, a proportional mortality study (as check of methodology which may be useful elsewhere), a case-control study of brain tumor deaths, and a cohort mortality study. Coding of company records is being completed and the case-control study will begin soon.

REGISTRATION OF DIOXIN WORKERS

W. Halperin, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C21-659)

Tetrachlorodibenzo-p-dioxin (TCDD) is a highly toxic contaminant of manufacturing processes which use trichlorophenol as a feedstock. The manufacture of the herbicide 2,4,5-T is an example. TCDD is a chloracnegen and acute toxin as well as a carcinogen and a teratogen in laboratory animals. In its use as a defoliant, large numbers of people have been exposed.

We propose establishing a registry of workers who have been exposed to TCDD during manufacture of TCP and other compounds. This registry may serve as a base for cohort mortality studies and for possible studies of reproductive effects and morbidity.

CASE CONTROL STUDY OF GOODPASTURE'S SYNDROME ETIOLOGY

W. Halperin, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-622-600)

Goodpasture's Syndrome (GPS), a rare but devastating form of renal failure, is characterized by necrotizing glomerulitis and life threatening pulmonary hemorrhage. Consistent with an occupational disease, GPS is more common in males than females, and more common in younger rather than older adults. The etiology is thought to be autoimmune, although tentative associations with influenza and hydrocarbon solvents are alleged. One study documents prominent solvent exposure in six of eight cases interviewed, but no assessment of exposure in controls was attempted.

A case control study of the causes of GPS will require nationwide interviews of 75 cases and 150 controls. Methods of case ascertainments are now being explored.

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF FUELMEN

W. Halperin, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (CMH-C22-657)

Workers who load jet fuel (kerosene) into commercial aircraft at JFK Airport in New York are exposed to kerosene, carbon monoxide from vehicular exhaust, and aircraft exhaust which include aliphatic and aromatic hydrocarbons. A preliminary investigation in response to alleged unusual death rates has uncovered several findings: 1) two of 31 deaths are due to multiple myeloma which represents an unusual fraction, and 2) maintenance and design of vehicles may allow excessive exposure to carbon monoxide. A cohort mortality study with industrial hygiene characterization of the worksite is planned.

2.0374,

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO TETRAETHYL LEAD

M. Haring, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C21-656)

Preliminary epidemiologic investigation of employees of one company involved in the production of tetraethyl lead has revealed three cases of multiple myeloma, two living and one deceased. These three cases represent approximately 30 times the rate expected. More comprehensive case ascertainment is being proposed to locate other diagnosed cases, both living and dead, in the same workforce. This will be accomplished by expanding a continuing retrospective cohort mortality study conducted by the company and by mailing questionnaires to former and current employees. Dependent on the results of more extensive case findings, it is proposed to screen the population for asymptomatic multiple myeloma. Multiple myeloma often demonstrates a lengthy course prior to diagnosis. The cost of laboratory tests might range from 40 to 70 dollars per person.

The industrial hygiene portion of this project will include both preliminary and in-depth characterizations of the work environment in the tetraethyl lead production areas. Personal and area monitoring for tetraethyl lead, the reactants in the production process, and other additives used in the blending operations will be included.

INDUSTRIAL HYGIENE CHARACTERIZATION OF PETROLEUM REFINERY TURNAROUNDS

C. Cox, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-E22-682)

The petroleum refining industry is one of the most complex industries in the U.S. although not necessarily one of the most technically up-to-date industries. Only three new grassroots petroleum refineries have been constructed in the U.S. since 1971. To insure that unit operations within these refineries remain on line, regular on-line maintenance is programmed. However, unit operations must periodically be taken off-line (closed down) to perform a complete overhaul or major maintenance. In the refining industry, this would be defined as a 'turnaround'. Most of the turnaround work is done by outside contract firms. Current literature reviews and contacts within the petroleum industry indicate that very little is known about the injury and illness associated with these activities. Depending on the unit operation on which the turnaround is being performed, the workers will be potentially exposed to virtually a shopping list of toxic and carcinogenic chemicals.

The purpose of the project is to identify and quantify worker exposure during turnaround activities at the catalytic cracker, coker, and asphalt units. The industrial hygiene characterization of these units would complement the current project 'Industrial Hygiene Characterization of Petroleum Refineries' which is documenting worker exposure to selected carcinogens during normal on-line operations of these three refinery units.

VIBRATION AND INDUSTRIALLY RELATED LOW BACK DISEASE

J.W. Frymoyer, University of Vermont & State Agricultural College, School of Medicine, Dept. of Orthopedic Surgery, *85 S. Prospect St., Burlington, Vermont* 05401 (R01 OH 00745-02S2)

Epidemiologic and mechanical studies suggest that cyclic loading is an important etiologic risk factor in the development of degnerative disc disease. Posture, spinal stiffness, asymmetric spinal loading and abdominal tone appear to influence the effects of vibration. By analysis of a general practice population and questionnaire survey, we will define the role of cyclic loading in the broader perspective of low back pain (LBP). Sub-groups with and without back pain, with and without significant vibrational loadings will be identified. These sub-groups will then be investigated by questionnaire, and by standardized physical examination for spine stiffness, posture, straight leg raising, and neurologic abnormality, using biomechanical test methods including Moire fringe topography. Psychologic factors will be evaluated by computerized modified Minnesota Multiphasic Personality Index (MMPI), pain drawings and tolerance tests. Objective radiographic analysis will correlate LBP with postural, congenital, disc space height, and facet characteristics. The load deflection and impedance characteristics will be measured. By case studies, the environmental vibrational stresses, lifting requirements, and asymmetric loading configurations imposed on the spine will be analyzed. (Safety standards will be recommended for vibrational stresses.)

OCCUPATIONALLY-INDUCED ISOCYANATE REACTIONS

I.L. Bernstein, University of Cincinnati, School of Medicine, Dept. of Internal Medicine, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221 (R01 OH 00773-02)

Isocyanates are widely used in the plastics industry for preparation of polyurethanes. Adverse effects of various isocyanates such as asthma and contact dermatitis are well-recognized occupational hazards. This proposal is designed to investigate the immunological basis of these isocyanate reactions. Immunological effects of aromatic diisocyanate (TDI toluene diisocyanate) and aliphatic diisocyanate (HDI hexamethylene diisocyante) will be studied in both animals and humans. Various isocyanate-protein conjugates prepared under controlled laboratory conditions will be characterized by determining precise adduct-carrier ratios. Inducton of homocytotropic and precipitating antibodies by isocyanate-protein conjugates will be investigated in guinea pigs and mice. Effects of chronic inhalation of isocyanate compounds and protein conjugates will be studied in guinea pigs. Investigation of humoral and delayed hypersensitivity will be conducted in TDI- and HDI-sensitive workers. Bronchial provocation tests to isocyanate vapours and aerosol mists of protein conjugates will also be performed in sensitized workers.

ANESTHETIC EXPOSURE AND HEALTH OF DENTAL PERSONNEL

E.N. Cohen, Stanford University, School of Medicine, Dept. of Anesthesia, *Stanford, California* 94305 (R01 OH 00775-02)

Recent epidemiologic studies indicate that chronic exposure to inhalation anesthetic gases may have a deleterious effect on the health of personnel employed in the operating room. A comprehensive study of exposed personnel in the hospital operating rooms of this country was recently conducted by the American Society of Anesthesiologists for the National Institute for Occupational Health and reported in 1974. This major study confirmed the findings of previous small-scale studies, all of which indicated an increase in the rate of spontaneous abortion and birth defects in exposed operating room personnel. There was also a significant increase in the incidence of liver disease and unexpected disclosure of a higher rate of congenital anomalies in unexposed wives of practicing anesthesiologists. The belated suspicion that a large segment of the dental profession might be similarly affected was given support when a small pilot study of dentistry disclosed similar serious health hazards.

The purpose of the present investigation is to study in detail the health histories of dentists, their wives, and auxiliary personnel numbering nearly 100,000 individuals. A unique opportunity in this effort will be the study of a large occupational group exposed to a single agent, nitrous oxide, versus the anesthetic gas mixtures.

A two-phase questionnaire survey has been designed to first identify those dentists who use and those who do not use inhalation anesthetics. The investigation will then concentrate on the health hazards of the users, ther wives and exposed employees. In turn, this group will be compared to a control group of non-inhalation anesthetic users. A carefully designed written questionnaire, fashioned after that used in the original ASA-NIOSH survey of hospital operating room personnel, will be employed. The questionnaire will be followed by written and telephone communications, ensuring a high response rate and adding validity to the overall health findings.

CANCER RISKS IN COSMETOLOGISTS

J.W. Meigs, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (R01 OH 00780-02)

This study will investigate the incidence of cancer of all sites among cosmetologists who were licensed in Connecticut before 1965, and will obtain a more definitive test of preliminary results which suggested that the cosmetologists have an icreased risk of acute leukemia. Follow-up status as of December, 1978 will be determined for all cosmetologists. The expected number of cases of cancer of individual sites will be: determined by applying to the group at risk the cancer incidence rates of the general Connecticut population, specific for age, calendar year, sex and site. Cancer cases will be ascertained through the Connecticut Tumor Registry.

JOB CONDITIONS, OCCUPATION, AND CORONARY HEART DISEASE

R.A. Karasek, Columbia University, School of Engineering & Applied Science, Dept. of Industrial Engineering & Operations Research, *Broadway & W. 116th St., New York, New York* 10027 (R01 OH 00906-01)

The object of this research is to examine U.S. data on cardiovascular disease and job conditions for associations similar to those recently obtained by these researchers in cross-sectional and prospective analysis of Swedish national data. Those findings confirmed the relationship between C.V.D. and psychosocial job characteristics using a previously untested model of job psychological strain development based on job decision latitude (low) and psychological job demands. These same job characteristics have been previously shown to be stress-related in both U.S. data and Swedish data based on comparable populations and survey instruments.

We propose to examine five major U.S. data bases including information on job characteristics and C.V.D. or C.H.D.: The H.I.S. (I972); H.E.S. (I960-62); H.A.N.E.S. (I970-75); the Western Collaborative Study; and the Framingham Study. While data measuring job characteristics is generally weak in all existing large scale U.S. C.V.D.-C.H.D. data bases, the above surveys do contain either limited direct measures of the relevant job characteristics or detailed U.S. Census Occupational Codes (382 categories). These codes can be used to indirectly assess job condition impacts with the help of job characteristic-occupation data in three national U.S. working condition surveys (I969, I972, I977). The U.S. data bases also allow isolation of the unique contribution of job conditions to C.V.D. risk, through multivariate control for conventional risk factors (especially age, smoking, serum cholesterol, type A behavior and socioeconomic status). It should be noted that our model, based on work environment conditions, represents an alternative psycho-social mechanism of disease development to that implied by current 'Type A' behavior research (based on personality characteristics). Also, previous U.S. and Swedish findings based on the model have not substantially weakened when socioeconomic status is controlled.

The presently available U.S. data probably cannot provide the final assessment of job-related C.H.D. risk. Our proposal makes maximum use of the extensive existing data resources, and should provide a basis of more exact data collection instruments in the future. Our project output will include a recommended job analysis instrument.

LUNG CANCER SCREENING OF WORKERS AT HIGH RISK

C. Mittman, City of Hope Medical Center, Dept. of Respiratory Disease, *1500 E. Duarte Rd., Duarte, California* 91010 (R01 OH 00914-02)

Through a longitudinal study of approximately 6000 coke-oven workers we will characterize the histopathology of lung cancer occurring in this high-risk occupation and determine if repeated sputum cytology studies reveal a sequence of changes leading to lung cancer. We seek also to determine if coke workers who develop lung and other cancer have elevated levels of tumor markers such as serum CEA, serum and urine polyamines. We will try to ascertain if the presence of tetraploidy characterizes cells in lung cancer. Factors influencing these changes will be examined, especially cigarette smoking history, job location and duration. This information will be used to propose cancer control strategies for this group of workers.

OCCUPATIONAL HEALTH RISKS OF WORKERS IN ATOMIC PLANTS

T.F. Mancuso, University of Pittsburgh, Graduate School of Public Health, Dept. of Industrial Environmental Health Sciences, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (R01 OH 00929-01)

The purpose of this research is to determine the occupational risks among workers in an atomic energy facility. A major objective is to study the long-term delayed biological effects of low-level ionizing radiation in a normal adult industrial population, who have been chronically exposed to fractionated doses of low-level ionizing radiation over a span of years. The study is a prospective epidemiological evaluation of workers employed since 1944 and in succeeding years to be followed for cause of death identification through 1979, in which known radiation measurements have been made and recorded on a uniform basis during the entire period of employment. The National Social Security System is utilized for the identification of the deceased and the state vital records provide the cause of death data.

A control population for the Hanford employees matched to the 35,000 atomic worker population has been established and will be processed simultaneously through Social Security with the employees for the identification of mortality data. Previous analyses have been confined to Hanford employees, 1976.

The research will enable the extension of the period of years of observation for a population of 150,000 with the incorporation of the matched controls, for the same period of time.

Successive cohort analyses of employee populations, with simultaneous control of employment exposures, employment patterns, occupations, and external and internal radiation measurements will be carried out.

ANESTHETIC METABOLISM - TOXIC EFFECTS IN OPERATING ROOM PERSONNEL

E.N. Cohen, Stanford University, School of Medicine, Dept. of Anesthesia, *Stanford, California* 94305 (R01 OH 00622-03)

The association between metabolism of the volatile anesthetics and long-term toxicity is well established. This toxicity is frequently seen as organ damage to the liver, kidney and reproductive system. An association between cancer and anesthetic exposure has also been suggested, and recent large scale epidemiologic studies in the U.S. and U.K. indicate an increase in female cancer among exposed O.R. personnel. The likely association between exposure to the waste gases in the operating room, anesthetic metabolism, teratogenicity, and carcinogenicity is based on studies indicating that irreversible effects result from anesthetic biodegradation. Our intent is to select two commonly used anesthetics, halothane and nitrous oxide, and investigate their metabolism. It is known that exposure to compounds such as vinyl chloride and the alpha-haloethers results in carcinogenesis, possibly related to the fact that these agents or their metabolites are powerful alkylating agents. It seems reasonable that a similar mechanism might apply in the case of the chemically related halogenated anesthetics. Halothane is known to be metabolized, but limited information is available concerning the reactive intermediates which covalently bind to the liver. These or similar molecules are likely to be involved in its potential toxicity and carcinogenicity. The metabolism of nitrous oxide remains to be confirmed. On a theoretical basis, its biodegradation to nitrites or nitrosamines would produce mutagenic and carcinogenic effects. Study of the metabolism of these two anesthetics, identification of their reactive intermediary metabolites and determination of their binding properties will help determine whether anesthetic metabolism is responsible for the observed toxicity. Such information will further guide our search for new and safer anesthetics and help establish standards for the protection of occupationally exposed operating room personnel.

PULMONARY DUST RETENTION & OCCUPATIONAL LUNG DISEASE

M. Lippmann, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016 (R01 OH 00678-02S1)

The retention sites and residence times for inhaled particles deposited in the non-ciliated pulmonary regions are important factors in the pathogenesis of major occupational respiratory diseases. This study is directed toward the quantitative characterization of the pathways, transport rates, and storage sites for respirable particles with defined size and shape and concentration. Particle retention within the thorax and tracheal lymph nodes following aerosol inhalation will be measured for at least 8 months in 4 donkeys by the external in vivo dectection of radionuclides within the particles, and for ferromagnetic particles, by remanent magnetism.

AN INVESTIGATION OF OCCUPATIONAL WRIST INJURIES IN WOMEN

D.B. Chaffin, University of Michigan, Ann Arbor Campus, School of Engineering, Dept. of Industrial & Operations Engineering, *Ann Arbor, Michigan* 48104 (R01 OH 00679-04)

Past experience has shown that there is a high incidence of chronic wrist injuries among workers who perform manual work in industry; this incidence is particularly high among female workers. For example, in recent five year retrospective study of a sewing plant that was studied in the current investigation, Wherle (1976) reported that 10.3 cases of carpal tunnel syndrome occurred per million man hours worked.

The proposed research is a continuation of a current investigation, the tentative results of which show that carpal tunnel syndrome causation has both worker and job attributes. Based upon the findings of the current study, recommendations to alleviate carpal tunnel syndrome at the work place will be proposed. The objective of this continued research is to validate the effectiveness of these recommendations, both theoretically and empirically.

A field study that will involve implementation of the recommendations so as to intervene in the pathogenesis of carpal tunnel syndrome at the workplace is planned.

To measure the effectiveness of the recommendations, it has been necessary to develop a test battery to evaluate functional hand performance and to establish test score distributions for symptomatic populations during the past year.

An anatomical study in which the types of intrawrist forces that create morphological tissue changes within the carpal tunnel is underway to evaluate the theoretical basis of the field recommendations. Papers have been submitted to the following journals: Journal of Biomechanics, Journal of Occupational Medicine, Archives of Physical Medicine.

BEHAVIORAL AND NEUROLOGICAL EFFECTS OF MERCURY

G.D. Langolf, University of Michigan, Ann Arbor Campus, School of Engineering, Dept. of Industrial & Operations Engineering, *Ann Arbor, Michigan* 48104 (R01 OH 00707-04)

A cross-sectional study of effects of industrial mercury exposure is proposed. At least 150 workers from the mercury cell chlor-alkali industry will serve as subjects. Tests will include recently developed electrophysiologic (nerve conduction) and short term memory functional measurements. Results from pilot studies of 40 workers conducted during our current longitudinal study indicate that these tests may be very sensitive in detecting the earliest subclinical effects of mercury exposure. A larger cross-sectional study is therefore necessary to evaluate the adequacy of current mercury exposure control methods.

Electrophysiologic measurements will include traditional clinical measurements of nerves of upper and lower extremities in addition to new slow conduction velocity measurements. Tests of short term memory will include recently developed measurements of memory scanning rate and precision measures of memory span. All tests utilize microcomputer administration or analysis and have been developed in our current research. Correlation analysis will be used to explore possible relationships between employees' urinary mercury histories and test results.

Tests similar to those mentioned above have been found to be extremely sensitive in detecting early effects of lead and carbon disulfide exposure in several large cross-sectional studies in Europe and the U.S. Our preliminary evidence strongly suggests that a similar study of mercury exposed workers must be performed to assure protection of health of these workers.

SHIPYARD ASBESTOS DISEASE - MORTALITY EXPERIENCE

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (R01 OH 00682-02)

An epidemiological mortality study will be undertaken to analyze the experience of a cohort of aproximately 4,000 shipyard workers, characterized by trade, employed in a major eastern shipyard in 1967 for at least ten years and traced through 1980. Since many of these men began work (and asbestos exposure) 1940-1955, their experience will provide important information concerning the cancer risk associated with asbestos shipyard exposure.

These data will provide information concerning two important questions: the extent and nature of asbestos-associated disease with low-level, intermittent, episodic asbestos exposure, an important problem in much of American industry, including construction and shipyard work. Second, there are now plus or minus 4,000,000 Americans currently (225,000) or formerly engaged in shipyard work at sometime 1940-1975. Available information indicates that this group is at high risk of developing cancer in the future. It is anticipated that the information in this investigation will assist in identifying criteria for the development of an optimum medical surveillance program, a matter of considerable practical importance.

INDUSTRIAL HYGIENE STUDY OF INSULATION MATERIAL WORKERS - EPA

R. Herrick, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluation & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-E22-582)

Members of the insulation trade have long been noted to experience excess mortality due to malignant and non-malignant respiratory diseases. Although much of this observed disease has been attributed to asbestos fiber exposures, the hazards associated with many of the other insulation materials used are unknown. Some of the commonly used insulation materials include: 1. Aluminum silicate (ceramic) fibers. 2. Asbestos fibers. 3. Bentonite clay. 4. Calcium carbonate. 5. Cork. 6. Fibrous glass. 7. Gypsum. 8. Hair felt. 9. Impregnanted paper. 10. Magnesium carbonate. 11. Polystyrene. 12. Polyurethane foams. 13. Portland cement. 14. Slagwool and rockwool fibers. 15. Vermiculite (expanded).

The purpose of the proposed research is to determine by literature research quantities of the various insulation materials used in the U.S., the number of workers potentially exposed to each material, and historic exposure levels. Current exposure levels of employees to two insulation materials will be determined through industrial hygiene surveys. A contract will be awarded to accomplish this project.

NEUROLOGICAL EFFECTS IN LEPTOPHOS EXPOSED WORKERS

C. Xintaras, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMR-622-675)

Medical findings from a recent health study of workers exposed to leptophos (Occupational Exposure to Leptophos and Other Chemicals, NIOSH Pub. No. 78-136, March 1978) revealed workers with slow or incomplete recovery from peripheral nerve damage and, in some instances, damage to the central nervous system suggesting upper motor neuron lesions. Through appropriate medical follow-up examinations, this project seeks to determine the reversibility of the observed effects and to better understand the significance of any diminished functional capacity to the demands of the worker's current and potential job opportunities.

All former and current workers with out-of-range values in NIOSH's first neurological/electromyographic examination will be contacted and asked to volunteer to be re-examined. Selected elements of the medical examination will be identical to those administered during NIOSH's first medical examination to ensure comparability of findings. Electrophysiological tests will be administered by physiatrists.

Results of this study will establish the reversibility of neurological effects in workers exposed to leptophos and provide information on the sensitivity of electrophysiological measures for the early detection of neurological effects in workers exposed to neurotoxic chemicals.

CYTOGENETIC EPIDEMIOLOGIC STUDIES

W. Halperin, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-W22-663)

It is well documented that cytogenetic changes or disorders have been associated in both animals and man with cancer, birth defects, and spontaneous abortions. Recent studies have associated environmental exposures, such as benzene, with increased levels of chromosomal damage as well as increased risk of cancer in exposed individuals. Studies of survivors of the atomic bombs in Hiroshima and Nagasaki have demonstrated an increase in chromosomal aberrations, birth defects in the offspring of the exposed parents, and a high incidence of leukemia. Results from two separate studies of individuals exposed to benzene have demonstrated an increased risk of leukemia and an increased incidence of chromosomal aberrations. However, the exact relationship between cytogenetic changes and cancer, birth defects, and fetal loss is not yet known.

This project will initiate studies to explore this relationship. population of workers exposed to a specific agent or working in a specific industry suspected to have mutagenic and/or carcinogenic potential will be selected for study. Peripheral blood samples will be obtained and analyzed for chromosomal aberrations. It is likely that the population selected will be already undergoing a reproductive history and, if feasible, a mortality study so as to maximize the yield of information on the substance under study. A contract or grant for cytogenic analyses will be developed and let.

MORTALITY STUDY OF CHEMICAL PLANT WORKERS IN THE KANAWHA VALLEY, WEST VIRGINIA

R. Rinsky, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C22-680)

The Union Carbide Corporation has begun a study of mortality patterns among its Kanawha Valley employees. Union Carbide plans to determine the vital status of all past employees and to analyze deaths by life table and case control studies.

Union Carbide has requested that the National Institute for Occupational Safety and Health (NIOSH) become involved in a joint venture. NIOSH would provide technical expertise, computer support, and limited follow-up, while Union Carbide would provide clerical staff for coding and would develop a history of the plant's operations.

NIOSH previously was involved in a similar effort with a Union Carbide study of its Texas City employees. This study will also be of value in the NIOSH study of Union Carbide Kanawha Valley workers exposed to ethylene oxide. There is opportunity for a number of cohort studies to be developed.

MORTALITY STUDY OF STEELWORKERS

J. Salg, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Surveillance Hazard Evaluations & Field Studies Division, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMO-C11-516)

PART I: A study of the Long Term Mortality Experience of Steelworkers was initiated in 1962 as a contract with the National Institutes of Health and the Department of Biostatistics, University of Pittsburgh, Graduate School of Public Health. Originally, data was collected on all male employees from seven Allegheny County steel plants. Since then, the study has expanded to include steelworkers throughout the United States and Canada. Although the investigation originally focused on coke oven workers, it has expanded to include all work areas within the steel industry. Important findings include the identification of lung cancer excess among coke workers, the excess of nonmalignant respiratory diseases among coke oven workers, and the positive association of increased risk of disease with increased length of exposure for coke oven workers. Mortality patterns have been described for other major work areas within the plant such as the foundry, the billet, bloom and slab mills, structural mills and the mason department.

PART II: In addition, we propose to review, organize and prepare for NIOSH publication detailed data already generated from the ongoing contract. Although the principal results have appeared primarily in a series of articles in the Journal of Occupational Medicine, presentation of detailed data in specific work areas of interest and a general update of steelworker mortality data are needed.

FY-78 ACCOMPLISHMENTS: Part I: Completion date has been pushed back to March 1979. Part II: Preliminary review of study data through 1970 has been completed.

2.0395,
MORTALITY, REPRODUCTIVE AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO MW-RF ENERGY
B. Egan, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C21-595)
RF/MW radiation has been implicated in a variety of biological phenomena including altered transmembrane potentials, increased membrane permeability, hyperthermia, hormonal imbalance, chromosomal anomalies and mutagenesis. Although their exact roles are unknown, similar phenomena have been implicated in carcinogenesis. In addition several unconfirmed allegations have been made associating exposure to microwave radiation with pancreatic cancer in radar repair workers, brain cancer in electronic workers and leukemia in the Moscow Embassy employees. Unfortunately, the size of the population potentially at risk in most of these case reports was too small to conduct a scientific evaluation of the situation. More recent research has indicated that exposure to RF/MW radiation can effect incidence of infertility and teratogenesis among study groups exposed to RF/MW radiation. The reported experimental and clinical results raise more questions than answers. Though these questions are both stimulating and suggestive, further research is required to critically assess both the potential carcinogenic hazards and reproductive hazards of RF/MW radiation. NIOSH has identified a cohort of radar repair workers that may be suitable for inclusion in an epidemiologic mortality study. This population would consist of all persons enrolled in the Electronic Apprenticeship Training Program which has been sponsored by the Naval Air Reworks Facility since the early 1950's. However, since this study population will only consist of about 1000 individuals and it may be difficult to obtain complete employment histories on all workers, additional walk through surveys and record assessments will be conducted in plants having microwave heat sealing, drying or baking operations before a final cohort is selected. If possible, a cohort will be selected that includes a large number of female employees so that a retrospective cohort mortality study and a reproductive study can be conducted on the same population. If a cohort with a large enough number of female workers can not be identified then the wives of male workers will be interviewed for a reproductive history.

2.0396,
MORTALITY AND INDUSTRIAL STUDY OF FOUNDRY INDUSTRY - NCI
B. Egan, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C22-616)
A preliminary report on a proportional mortality study of foundry workers demonstrated an excess mortality from lung cancer and nonmalignant respiratory disease (NMRD). Similar findings have been reported in other epidemiologic studies.
Excessive exposure to particulate dust, especially silica dust, is a logical explanation for the NMRD. However, there is controversy over whether silica exposure is still a problem in foundries today or whether the advanced control technology introduced into many foundries over the last 20 years has reduced the silica levels enough to prevent an excess NMRD risk.
Those specific etiologic agents responsible for the increased lung cancer risk have not yet been adequately identified. Two of the more recent epidemiologic studies of foundry workers conducted by Karava et al. in Finland and Gibson et al. in Canada included detailed industrial hygiene surveys as part of the study. Low levels of several suspect carcinogens were identified, but neither of these surveys was able to pinpoint specific agents as being associated with the excess lung cancer risk.
Studies to ascertain what chemical or physical agents may be associated with the excess lung cancer risk identified among foundry workers and what the incidence of silicosis is among those individuals who were first employed in a foundry after 1950 are needed.
A feasibility study will be initiated to collect additional detailed exposure data on the study population identified through the International Molders Union's death benefit fund. Selected locals of the Molders Union will be contacted directly to determine what type of information is available on deceased individuals, such as type of foundry where they were employed and/or specific jobs worked, and then case control study will be conducted to evaluate the work experience of the lung cancer cases.

2.0397,
EVALUATION OF SPECIAL OCCUPATIONAL HAZARDS
A. Gregory, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Criteria Documentation & Standards Development, *5600 Fishers Ln., Room 3-32, Rockville, Maryland* 20852 (VII-D50-093)
This project entails the review and evaluation of potential workplace hazards where new evidence of a particular or special hazard is received. As a result, special occupational hazard reports, which may include recommended occupational standards, including emergency temporary standards, will be prepared. The nature of the alleged hazard and urgency of the required response will dictate the procedures to be used as well as the report to be issued.
The Special Occupational Hazard Reviews will evaluate health effects, and existing exposures and control measures. Based upon such review, appropriate preventive measures may be recommended, including engineering controls, good work practices, safe materials handling, workplace monitoring, environmental exposure limits, surveillance methods, recordkeeping, etc.
Based upon the nature of the review, the report will be disseminated to the Department of Labor and/or to the occupational health community.
The evaluations will pertain primarily to special alleged hazards, e.g., carcinogenic, mutagenic, or reproductive effects, although they may review other effects as needed. During FY79 special hazard reviews were completed on trichloroethylene, ethylene dichloride, and MOCA.
This project also provides technical support to the Chemical Selection Working Group of the National Cancer Institute for determining chemicals to be selected for carcinogenicity testing.

2.0398,
CURRENT INTELLIGENCE SYSTEM
N.A. Leidel, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Criteria Documentation & Standards Development, *5600 Fishers Ln., Room 3-32, Rockville, Maryland* 20852 (VCF-G12-019)
The basic purpose of the Current Intelligence System is to promptly review, evaluate and supplement new information received or generated by the National Institute for Occupational Safety and Health (NIOSH) on occupational hazards which are either unrecognized or are more severe than generally known. As warranted by this evaluation the information is capsulized and disseminated to NIOSH staff, other government agencies, the occupational health community (which includes labor, industry, academia and public interest groups), and the general public. The Current Intelligence Bulletins prepared in this project describe measures designed to minimize human risks. This system also serves to advise selected members of the above groups of specific knowledge recently acquired by NIOSH which pertains to their particular occupational environments.
SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health $320,000

2.0399,
MORTALITY, MEDICAL AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO NITROGLYCERIN
G. Reeve, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-G21-669)
About 8000 workers are exposed yearly to nitroglycerin (NG) during its manufacture. Not only is work with this agent hazardous because it is explosive, but workers also suffer from acute toxicity (headaches due to vasodilation), may have excessive numbers of sudden deaths while employed (possibly from coronary vasospasm), and may suffer from excessive cardiovascular mortality after retirement.
An opportunity exists at the Radford Arsenal in Virginia to study cohort of 37 current workers and a much larger number of former nitroglycerin workers. A cohort mortality study (Va. deaths as comparison) would be valuable to establish the fact of excess death during employment and after separation. Since the plant physician has done periodic electrocardiograms and excluded workers with abnormalities from NG exposure, a potential exists to compare the mortality of NG workers with ECG abnormalities to NG workers with normal ECGs. This comparison would not be meaningful unless another group of non-nitroglycerin workers is followed in the same way.
These same groups would be used to determine if there is a characteristic NG abnormality on the ECG and also if abnormalities are present at the same rate in non-NG workers.
If there is excess mortality in workers long after separation from exposure, it will be valuable to investigate its cause by comparing heart disease risk factors in NG retirees compared with other retirees. Risk factors such as blood pressure, lipids, etc. would be evaluated.

2.0400,
MORTALITY STUDY OF WORKERS EXPOSED TO CARBON MONOXIDE
W. Halperin, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-G21-673)
Carbon monoxide is a commonly encountered industrial asphyxiant, and the effects of acute exposure have been fairly well studied. Although little is known about the effects of chronic exposure in man, ambient air levels have been linked to the probability of surviving a myocardial infarction. In animals, chronic exposure is linked with lowering of the ventricular fibrillation threshold. NIOSH has conducted a study of possible chronic effects from CO exposure in motor vehicle inspectors with chronic exposure of 15 ppm with equivocal results. An opportunity may exist to study car tunnel workers with exposures of 70 ppm.

2.0402,

MORTALITY STUDY OF POTASH WORKERS

R. Waxweiler, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-M22-664)

The long term effects of diesel exposures need to be thoroughly evaluated as diesel fuel begins to take on a more important role in our country's energy policy. An occupation believed to have fairly high levels of diesel exposures is underground mining. Although most mines would have many other confounding exposures such as asbestos, radon daughters, and arsenic, potash mines have presumably non-carcinogenic environments as determined by a previously conducted retrospective cohort mortality study of 2743 underground and 1143 surface potash miners (Waxweiler et al., J. Occup. Med. 1973). Diesels were introduced in these mines in the early 1950's. By extending the epidemiologic study from 1967 to include follow-up through 1978, a 25 year latency period could be evaluated for many of the miners. In-depth industrial hygiene surveys would characterize current worker practices. The control technology section of NIOSH has an analogous project to evaluate diesel exposures underground in relation to such parameters as duty time and preventive maintenance.

2.0403,

EPIDEMIOLOGIC STUDY OF WORKERS IN PETROLEUM REFINERIES AND PETROCHEMICAL PLANTS

R. Waxweiler, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C22-662)

An NCI study examined the cause-specific mortality experience of workers who were active members of Oil, Chemical and Atomic Workers International Union (OCAW) Locals in Texas at the time of death. Proportional mortality ratios (PMR's) for stomach and brain cancers, for leukemia, and for multiple myeloma were elevated among white males who worked in petroleum refineries and petrochemical plants and were Union members for at least 10 years. In particular, increased relative frequencies of stomach and brain cancer deaths were found among white male members who were employed at a refinery in Port Arthur (Plant A). In addition, PMR's were elevated for lung cancer among non-whites and stomach cancer in both racial groups employed at another refinery in Port Arthur (Plant B).

Observed numbers of deaths from leukemia, and from cancers of the kidney and skin were greater than expected among white males at Plant B, but observed numbers were very small.

A third refinery in Beaumont, Texas, was found to have excessive frequencies of lung and brain cancers among workers. A case-control study will be done as a timely second step to examine excess deaths from certain cancers in greater detail.

Detailed work histories will be obtained from each case control to determine length of employment in these plants, specific job(s) held, work location(s) within the plants, and any other employment or exposure information that is available.

The case-control study may be followed by a more definitive cohort study.

2.0404,

INDUSTRIAL HYGIENE/MORTALITY STUDY OF WORKERS EXPOSED TO SELENIUM

K. Wallingford, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-M21-666)

The U.S. produces and uses approximately 1.4 million pounds of selenium annually. All primary selenium producers are electrolytic copper refiners. Selenium compounds are manufactured by approximately 10 producers at various locations withing the U.S. Chronic selenium poisoning in test animals has been shown to have widespread effects with lesions occurring in all the internal organs. Selenium and its compounds have been shown to be carcinogenic in rats, and teratogenic for chicks, sheep, pigs, and cattle. In addition, chronic selenium poisoning has produced adverse effects in the reproductive system in rats, sheep, cattle, and other grazing animals. In industrial situations, workers exposed to elemental selenium in the form of fine dust have developed nosebleeds, loss of the sense of smell, inflammation of respiratory mucous membranes, and dermatitis.

The purpose of this project is to conduct an industrial hygiene/retrospective cohort mortality study of workers exposed to selenium to evaluate the long term effects. The first phase of the investigation will be a study to determine the extent of exposure, to characterize the work environment, and to assess the feasibility of conducting the mortality portion of the study. The second phase, if initiated, will be a comprehensive industrial hygiene characterization and retrospective mortality study of the selected site(s).

2.0405,

SPONTANEOUS ABORTIONS AMONG EMPLOYED WOMEN

B. Albright, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-W22-665)

NIOSH periodically receives inquiries about complaints of fetal loss from women employed in various work places. Beyond the generally accepted estimate of gynecologists that about one pregnancy in ten terminates in spontaneous abortion and one well-controlled study in Hawaii with few white participants, there are no reliable standards to which we can compare the experience of a group of women. Furthermore, effects of prior abortions on the probability of successful completion of a present pregnancy are not well documented.

This study would seek to establish rates for spontaneous abortions in a variety of working populations through the following steps: 1. Concurrent literature review and consultation with experts or organizations interested in pregnancy outcome to assure that this information is not already available. 2. Feasibility study to ascertain whether large national organizations with sizable constituencies of young women would assist in this type of study. Organizations for consideration may include the National Education Association; the International Ladies Garment Workers Union; the American Federation of State, County, and Municipal Employees; and female federal employees. We would be looking for cohorts with differing socio-economic and regional backgrounds but without high exposures to toxic agents. 3. If a cohort could be found, members planning to become pregnant would be asked to register with NIOSH. Each woman would be given a log book in which to record each menstrual period and a home pregnancy detection kit. Each participant would be given a questionnaire dealing with demographic data, past pregnancy history, etc.

OCCUPATIONAL RESPIRATORY DISEASE STUDY - D.O.L.

J. Merchant, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKA-R50-104)

In Section 17 of the Black Lung Benefits Reform Act of 1977, the Secretary of Labor in cooperation with the Director of NIOSH was asked to conduct a comprehensive study of occupational respiraory disease. This study was to include definition, clinical aspects, epidemiological aspects, State and Federal compensation programs, and State and Federal legislation dealing with occupational safety and health legislation. Under an Interagency Agreement with ASPER, the Department of Labor, and Division of Respiratory Disease Studies, it was agreed that a report would be prepared covering occupational respiratory diseases in some detail. This report will be completed largely on task order contracts with experts dealing with various respiratory diseases. It is anticipated that this report will be completed by the end of the 3rd Quarter of FY'79.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health $220,357

2.0407,

EPIDEMIOLOGIC STUDY OF NORMAL BLUE COLLAR WORKERS

M. Petersen, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKL-R32-227)

Nonexposed blue collar workers will be examined using DRDS staff, equipment, and techniques for use as controls for epidemiological studies conducted at ALOSH. Participation is voluntary and data will be collected by a mobile field team. The subjects will be grouped by combinations of sex, race, and smoking habits in the analysis, and estimates of prevalence rates of symptoms and disease as well as standard pulmonary function equations will be developed for each combination.

In addition, the project will be expanded to compare other areas of the country to the North Carolina area.

2.0408,

3RD ROUND NATIONAL STUDY OF COAL-WORKERS' PNEUMOCONIOSIS

M. Attfield, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Respiratory Disease Studies, *944 Chestnut Ridge Rd., Morgantown, West Virginia* 26505 (VKL-R22-183)

In the area of coal research, it is mandatory that a large and stable group of miners be studied over a long time period. The many relationships between dust, radio-graphic evidence of disease, and pulmonary function can thus be studied. Moreover, a data base is being developed which should be helpful in future mortality studies.

The data base being developed is a pool of information wherein selected facets of the problems associated with CWP can be studied. The data base is open to all investigators in ALOSH.

The data base development is a consequence of close cooperation between the Epidemiological Investigations Branch, the Environmental Investigations Branch, and the Examination Processing Branch of ALOSH. The data (spirometry, symptomatology, demographic and anthropometric measures, and chest radiographs) are obtained by the field team from the miners at the mine site. The mines have been pre-selected to represent a cross-section of mining methods, type of coal, and other factors so as to be representative of the U.S. coal industry. From round to round, if a particular mine closes, a new one is added or in some instances, new ones are added to expand the data base. Once the data have been collected, it is checked, coded, punched to tape, verified, and in general, processed by the Statistics section and the Examination Processing

Branch. Several types of magnetic tapes are generated and these tapes are continually updated.
Analyses of the data is done concurrently with the processing.
Additions to original cohort of mines made solid and most advance negotiations with companies and union completed.

2.0409,
MORTALITY AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO SULFURIC ACID - EPA
J. Beaumont, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Surveillance Hazard Evaluations & Field Studies Division, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH E21-579)
The EPA in its CHESS report (1970-1971) studied seven U.S. cities for community exposure to air contaminants. One community had a primary exposure to sulfur oxides and particulates. The findings of the CHESS report strongly suggest that occupational exposures to sulfur pollutants need further study in terms of exposure levels and morbidity and mortality.
The Proceedings of the Computer-based Conference on 'Human Response to Sulfur Pollutants' at Brookhaven Laboratory (1974) suggested that sulfates and sulfuric acid could have a possible carcinogenic and/or co-carcinogenic effect.
The purpose of this project is to conduct a retrospective cohort mortality study of a population occupationally exposed to sulfuric acid mist.
Pulp facilities, sulfuric acid plants, and copper sulfate processes have been eliminated as suitable cohorts. Several battery plants have been visited to determine their suitability for inclusion in a cohort mortality study. A contract has been awarded to Enviro Control, Inc. to locate a cohort and conduct a retrospective mortality study. Industrial hygiene assessment of the study plants will be conducted by NIOSH.
SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health $44,000

2.0410,
MORTALITY STUDY OF WORKERS EXPOSED TO FIBROUS GLASS - EPA
D. Bayliss, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Surveillance Hazard Evaluations & Field Studies Division, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-E22-585)
Much controversy has arisen over the possible carcinogenicity of fibers of small diameter. One group of scientists believes that the carcinogenicity of such fibers is related not to their physiochemical properties but more to the morphology of the particle. Several recent studies have provided evidence that tends to support both positions. historic follow-up study of workers at an Ohio fiberglass plant failed to demonstrate any excess of cancer over expected when followed for over thirty (30) years.
In the historic follow-up study most members of the cohort under study were never exposed or minimally exposed to small diameter fibers, with certain exceptions. However, during the 1940's, a process existed that produced small diameter fibers at this plant. While this 'pilot plant' operation existed, approximately 450 employees were exposed to small diameter fibers for varying lengths of time.
It is proposed that in order to assess whether this group of employees suffers from unusual cancer mortality a matched control group be selected from the non-exposed segment of the same population, matched according to date of birth and beginning date of employment, and cancer mortality of the exposed be compared to that of the non-exposed controls. (The population consists entirely of white males.) It is proposed that two controls be selected for each exposed employee.
After the selection of the controls, follow-up will be accomplished on the approximately 450 exposed and their approximately 900 non-exposed controls. Mortality due to lung cancer in the 'exposed' will be contrasted with that of the 'non-exposed' after analysis is complete. Relative risk of lung cancer will be examined at various periods from initial exposure and contrasted with that of the 'non-exposed' controls. Altogether follow-up will be accomplished on some 1900 former employees of this plant, i.e., 450 'exposed', 900 'non-exposed', and 550 large fiber 'exposed' employees.

2.0413,
HEALTH HAZARD EVALUATION DATA BASE
V. Behrens, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMO-G11-576)
Section 20(a)(6) of the OSH Act of 1970 charges DHEW with the responsibility for evaluating the potential toxicity of chemicals used or found in the workplace upon receipt of a written request from an employer or employee representative. The Hazard Evaluation and Technical Assistance Branch of NIOSH has been performing these on-site toxicity determinations without cost to the requestor since 1971. Although the procedure for responding to requests does not result in evaluation of sample worker populations representative of larger such populations, the surveys are unique for their combination of indepth environmental and medical investigations of particular industrial estabishments.
Selected information will be abstracted from all health hazard evaluation and technical assistance reports, including both past and currently generated reports, in a form suitable for computer input. Once this data has been transferred onto computer tape (or disk) it will be analyzed, using descriptive statistical techniques.
The Health Evaluation Data Base should demonstrate usefulness in an occupational health surveillance program. Significant health-related events or situations occurring in the U.S. worker groups can be monitored through comparisons to similar or contrasting occurrences in the past several years. The Data Base will facilitate these comparisons. Analysis can be accomplished for several variables (several of which are quantitative) to determine the factors for which ongoing or current occupational health-related events or situations deserve special consideration or study.
FY-78 ACCOMPLISHMENTS: Completed the abstracting, and coding from HHE and TA Reports for the period Jan. 77-June 78. Initiating creation of computer-based data file.
SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health $87,000

2.0414,
EPIDEMIOLOGY AND INDUSTRIAL HYGIENE STUDY OF ALUMINUM REDUCTION WORKERS
D. Brown, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMH-C22-563)
Workers in the aluminum reduction industry are exposed to a variety of substances, hydrogen fluoride fumes, dust, carbon monoxide, and coal tar pitch volatiles (CTPVs) such as benz(a)pyrene. CTPVs are released in the anode preparation area in plants using pre-baked anodes and in the pot lines where Soderberg self-baking cells are used. The release of CTPVs is thought to be temperature dependent. Sufficiently high temperatures are reached in both anode preparation and electrolysis of aluminum to achieve the release of such materials. Thus, there is concern for the health of aluminum workers who may be exposed to carcinogens within CTPVs such as benz(a)pyrene.
Industrial hygiene surveys of the aluminum reduction industry have revealed levels of CTPVs well above the current occupational health standard of 0.2 milligrams per cubic meter by the benzene soluble fraction method. A variety of studies have been carried out to describe the cancer mortality experience of workers in aluminum reduction facilities. Milham (1976) has reported an increase in proportionate mortality from total cancer, cancer of the pancreas, cancer of the respiratory system, and malignant lymphomas among aluminum workers in Wahington State. In a study by Equitble Environmental Health, cause-specific standard mortality ratios calculated for subgroups in the study population defined by major process showed a positive association between employment as a potroom worker and lung cancer, leukemia, and lymphoma.
In order to more fully define the specific cancer risk within the potrooms, a retrospective case control study is planned on aluminum workers exposed to CTPVs. Industrial hygiene will assist in classifying job categories and in verifying related industrial hygiene data. The case control study will use existing data generated from the Equitable study. The uses and controls have been selected from the Alcoa plants and the work histories have been coded.

CASE-CONTROL STUDY OF REPRODUCTIVE OUTCOMES
V. Behrens, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evlauations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMO-W11-507)
As part of the development of nationwide capabilities to assess occupational health effects and hazards, the Surveillance Branch has emphasized the use of existing sources of relevant comprehensive data. Information derived from the use of existing data sets should help in the identification of high risk occupational groups and the prioritization of research needs.
In the study of occupationally-related illnesses it is now important to assess the mutagenic and teratogenic effects on mothers and the mutagenic effects on fathers from reproductive hazards in the workplace. In the report of the NIOSH Work Group on Occupational Mutagenesis, Teratogenesis and Transplacental Carcinogenesis (November 5, 1976)

and a report and recommendations for the office of the Secretary DHEW on Occupational Health Problems of Pregnant Women (Vilma R. Hunt, April 30, 1975), recommendations were made to give high priority to the analysis of data already collected on pregnancy outcomes in relation to parental employment.

Through the publication of a sources sought synopsis (No. R-2-78) in the Commerce Business Daily on November 10, 1977, it was determined that a number of data sets are available for a study of pregnancy outcome in relation to parental employment. This project will abstract, code, computerize and analyze an existing data set, which includes among other elements occupational histories of parents and medical records of pregnancy outcomes, by a case-control approach to identify possible relationships between occupation and pregnancy outcome.

PREDICTION OF LUNG CANCER RATES FROM SPUTUM CYTOLOGY - EPA

V. Archer, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, Division of Surveillance Hazard Evaluations & Field Studies, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226 (VMA-E32-638)

Over 50,000 sputum samples have been collected from uranium miners since 1956. The collection has been financed by NIOSH, NCI, and ERDA. The sputum data, along with demographic data, have been put on computer tape and submitted to NCI for analysis. Analysis will be done in several ways, but the most important will be selection of individuals who had certain readings (e.g., Class III) on or before a certain date, then ascertaining deaths among the groups, and doing a life table mortality analyis to determine lung cancer incidence at 5, 10, 15 etc. years. This will be done for most classifications, and will give predictive values for each classification. This will probably apply to other groups as well as uranium miners, but actual study might be needed for verification. Progression from one sputum class to the next higher classification has been demonstrated in many individuals, with a mean of about 5 years between steps. Many individuals show progression. Sputum cytology is now used as a screening service for lung cancer among high risk populations. Many improvements in sputum cytology have come from these studies, and the lives of some uranium miners have been saved.

A contract is planned to collect morbidity and mortality data (and sputum samples where available) on about 500 individuals who have not responded to mailed requests for sputum samples. This will fill a gap in the sputum follow-up which is present in the data. A re-reading of many of the old slides will be done to strengthen the associations. The major activity in this project will be through the proposed contract. It is necessary because the follow-up requires contacting many former miners who are widely scattered. Information must be obtained on changes in their cigarette usage, changes in occupation, changes in sputum cytology, and changes in health.

2.0417,

LONG TERM EFFECTS OF PRENATAL X-RAY ON HUMAN FEMALES

M.B. Meyer, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 FD 00654-06S1)

This long-term epidemiologic study was designed to investigate possible effects of x-ray exposure during fetal life on the subsequent development, health, and reproductive experience of human females, and to detect possible adverse effects on their children. The study population comprises 1458 females exposed in utero to maternal diagnostic x-ray such as pelvimetry, 1458 individually matched unexposed females, and 189 exposed females for whom no controls were available. All were born in Baltimore City in 1947-1952.

Previous phases of the study have shown a 10-15% increase in fertility among women exposed in utero that occurs early in reproductive life. This statistically significant difference (p equals .011) remained after adjustment for differences between exposed and control women in economic, social and medical factors. Information about their survival, health, mental and physical development, reproductive history and child problems has now been obtained from these women by direct follow-up during their twenties (1973-1977). Preliminary analysis of questionnaire data suggests some possible exposure-related differences in growth, development, and reproductive experience.

We propose analysis of data from these questionnaires, linked with data from the previous studies and including a) details related to their mothers' pregnancies when they were born; b) details of registered births to the study women (1960-1972). The matched pair design, coupled with the rich variety of data from three generations, makes it possible to obtain exposed-control comparisons controlling most important extraneous independent variables. This will be accomplished by post hoc matching, by multiple cross-tabulations, and by multiple logistic regression analysis. A group of women for whom no controls were available because x-ray pelvimetry was so routinely used at the time of their births will be analysed for corroboration of positive or negative study findings.

EPIDEMIOLOGICAL STUDIES TO INVESTIGATE THE POSSIBLE ASSOCIATION BETWEEN ARTIFICIAL SWEETENERS AND INCREASED RISK OF CANCER

R. Hoover, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Environmental Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205

This investigation is being carried out in five states and four metropolitan areas: New Jersey, Connecticut, Iowa, New Mexico, Utah, Detroit, San Francisco-Oakland, New Orleans, and Atlanta. All but New Jersey are members of the nationwide Surveillance, Epidemiology, and End Results (SEER) network. Inclusion of New Jersey is necessary because of a unique population base and a reporting requirement. New Jersey has the highest bladder cancer mortality rates in the U.S. for males and females.

This study employs a case-control design using incident cases of newly diagnosed histologically confirmed primary carcinoma of the urinary bladder. All cases reside in one of the specified areas. Non-carcinomas are not included, e.g. paragaglioma, melanoma, sarcoma, lymphoma. Malignant papillomas and carcinomas in situ are included. Cancer of other sites in the urinary system are not included. The study population consists of subjects between the ages of 28 and 85 years.

Approximately 3000 cases enrolled in the study, two-thirds of them 65 years old or older, three-fourths of them males, and most of them white. An additional 800 cases are expected from New Jersey. The control series is a stratified random sample of the general population in each area defined by sex, race (white and non-white) and age (in five year intervals). In each area, twice as many controls as there are cases (6000 from the SEER program and 1600 from New Jersey) were randomly drawn from each stratum.

2.0419,

EPIDEMIOLOGICAL STUDIES OF OUTBREAK OF METHYLMERCURY POISONING IN IRAQ

T. Clarkson, University of Rochester, School of Medicine & Dentistry, Dept. of Radiation Biology & Biophysics, *601 Elmwood Ave., Rochester, New York* 14627

In preliminary studies of dose-effect and dose-response relationships in the Iraq outbreak of mercury poisoning, it was noted that the type of effect depended on the dose (estimated in terms of maximum body burden). Paresthesia was the first symptom with ataxia, dysarthria, and deafness manifesting themselves at higher body burdens. Although several previous findings have been confirmed in the preliminary studies, many questions remain unanswered. It is expected that the extensive followup studies will more precisely determine the dose-effect, dose-response relationship for pre- and early post-natal exposure. More detailed retrospective analysis will be made of clinical data already collected on infant-mother pairs where exposure took place during pregnancy. The clinical effects shall include evidence of delayed development and neurological signs of damage. Symptoms in the mother, such as paresthesia, will be included. The hypothesis to be tested is that the frequency of adverse effects in the infant should be elated to: 1) the peak concentration of mercury that occurred during pregnancy, and 2) the time during pregnancy when mercury attained a peak level. The cohort of children now under study has just entered school. Further interviews will include the school teachers who will be questioned concerning the children's behavior, learning ability, and class standing.

LONG-TERM HEALTH EFFECTS OF PBB EXPOSURE IN MICHIGAN

K. Wilcox, State Dept. of Public Health, *3500 N. Logan St., Lansing, Michigan* 48914

Polybrominated biphenyls (PBB) were dispersed widely in Michigan in a 1973 shipping accident through which PBB was introduced into cattle feed. Human exposure resulted principally from ingestion of contaminated dairy food products. To determine whether PBB exposure has caused illness, a prospective cohort study of 4,545 persons was undertaken. Three exposure groups were sought: all persons living on PBB quarantined farms; persons who received food directly from such farms; and workers (and their families) engaged in PBB manufacture. Enrollment rates were 95.6, 95.1 and 78% respectively. Also enrolled were 725 persons with low level PBB exposure. All were queried concerning 16 symptoms related possibly to PBB. Venous blood was drawn on 3,639 and analyzed for PBB by gas chromatography. Median serum PBB levels were 4.5 ppb in workers, 4.0 ppb in quarantined farm families, 3.0 ppb in recipients and 2.0 ppb in the low exposure groups. Preliminary evaluation failed to show associations between serum PBB levels and symptom prevalence rates.

Subsets of the cohort have participated in studies concerning human reproduction, biochemical abnormalities, and PBB distribution in human tissues. Data collected during the initial phase of the study is being evaluated with the assistance of outside statistical consultation. The study has now entered the long-term follow-up phase. Regular cycles of medical information update, medical diagnostic confirmation of reported problems, blood collections for PBB testing, and continuous registry update are under way. In addition, a cohort of 200 rural subjects in Iowa is being established as a comparison group.

INVESTIGATION OF THE INFLUENCE OF HORMONAL CONTRACEPTIVES ON THE CYTOLOGY OF THE CERVIX AND ON OUTCOME OF PREGNANCY

G. Zarcovic, Inst. of Hygiene & Social Medicine, *Sarajevo, Yugoslavia* (02-603-F)

One portion of the study is attempting to determine whether there is any relationship between oral contraceptive drug use and abnormal Papanicolau smears or cervical histology by comparison with a control group using mechanical contraceptives. The second portion of the study will seek to determine whether any relationship exists between oral contraceptive drug use and the occurrence of congenital anomalies in offspring.

Since the mission of the Food and Drug Administration is consumer safety, it is hoped that this study will contribute to our knowledge of the effects of oral contraceptives.

STUDY OF LONG-TERM EFFECTS OF DRUGS USED IN THE TREATMENT OF CHRONIC DISEASE

D. Slone, Boston University, School of Medicine, Dept. of Medicine, *80 E. Concord St., Boston, Massachusetts* 02215

The primary objective of this study is to determine increased risks of common chronic diseases, such as cancer and heart disease, in individuals who are exposed to regular and long-term drug therapy. A non-specific case control surveillance methodology is employed in which individuals entering the hospital are routinely questioned by trained nurse-surveillance officers about lifetime drug use, pertinent patient demography, medical and other exposure histories. Admission and discharge diagnoses are obtained. These data are computerized, screened and statistically/medically analyzed for the presence of causal relationships suggestions between drug use and subsequent development of disease. Over 30,000 individuals have been monitored thus far, and a number of articles on the methodology as well as specific findings produced by employment of this drug surveillance approach have been published.

2.0423,

HEALTH SIGNIFICANCE OF FOODBORNE PARASITES

G.J. Jackson, U.S. Dept. of Health & Human Services, Public Health Service, Food & Drug Admin., Bureau of Foods, *200 C St. S.W., Washington, District of Columbia* 20204 (04137)

STATEMENT OF OBJECTIVE: Determine the incidence and pathogenic potential of parasitic animals that occur in foods and in such food-contact materials as sewage that has been recycled as fertilizer or irrigant. Study methods for the inactivation of parasites in the food chain. Prepare technical and general information on the safety of foods in respect to parasites.

DESCRIPTION OF WORK: 1. Ascaris and Trichuris. Infections from Recycling of Fecal Wastes into the Food Chain. Due to legislation, wastes can no longer be disposed of into inland waters and, after 1981, into the ocean. Burning is expensive and contrary to clean air regulations. Consequently, more municipal, industrial and agricultural waste is being disposed of on land or is purposely entering the food chain. Eggs of such roundworms as Ascaris and Trichuris are the longest-surviving pathogenes in sewage, wastelage, soils and crops. Methods for monitoring have been studied. The choice method, Nacconol centrifugation, will now be tested and standardized in a collaborative study. Allergic symptoms similar to asthma, are frequent consequences of ascariasis and related roundworm (nematode) infections: these will be studied in experimental hosts (minings). 2. Giardia. Infections from Fecally Contaminated Foods. These flagellated protozoa have become, in recent years, the most common cause of parasitic diarrhea. Epidemics have been traced to water, but the survival of Giardia cysts on foods has been suspected rather than proven. The possibility of recovering Giardia cysts with the Nacconol centrifugation method developed for roundworm eggs will be studied jointly with MCMI. The food-related epidemiology of giardiasis will be studied collaboratively with the Medical Academy of Poznan (through PL-480 Collaborative Agreement 05-639-F with Poland). Judging the viability of Giardia cysts will be studied in-house using cultures and experimental animals. 3. Fishborne Anisakine Infections. Due to the increasing consumption of raw and semiraw fish, human anisakiasis is being reported in the USA. While FDA has already accomplished much work on these parasitic nematodes, several problems remain to be solved. This year we will determine the incidence of anisakines in the growing Hawaiian fish supply (contract); Standardize (in collaboration with t (Text Truncated - Exceeds Capacity)

2.0424,

FOOD CONSUMPTION, DIET AND HEALTH

R.G. O'Dell, U.S. Dept. of Health & Human Services, Public Health Service, Food & Drug Admin., Bureau of Foods, *200 C St. S.W., Washington, District of Columbia* 20204 (10219)

STATEMENT OF OBJECTIVE: To obtain data on mans dietary and environmental exposure to essential nutrients and other substances which affect the absorption and metabolism of these nutrients for the purpose of assessing the effect of the interrelationships on the general nutritional and health status of selected populations.

DESCRIPTION OF WORK: Food Consumption Habits, Nutrient Intake and Health (contract): A steering committee will be established by the contractor to conduct an in-depth study of FDA's needs for data on nutritional status as affected by food consumption. The contractor will also devise alternative methods for obtaining information on food consumption, study factors associated with food consumption patterns and design a model system for combining data on food consumption and nutritional health status.

Monitor Amino Acids for Inborn Error Diets (contract): In order to better monitor inborn errors of amino acid metabolism information on the clinical usage of special dietary products is needed. The contractor shall provide expert advice on the safety and usefulness of these products in the dietary management of children with inborn errors of amino acid metabolism. Also in cooperation with the Genetic Centers directors, the contractor will develop a system to collect uniformly pertinent clinical, biochemical and dietary data from the usage of new amino acid products in the management of patients with inborn errors of amino acid metabolism.

Food Consumption Data on Children Identified as Having High Blood Lead (contract): In this study, the contractor will compile information on the amounts of various foods consumed by children having high blood lead levels from dietary records recorded during case studies. Records on approximately 5,000 children will be compiled to provide the data base from which correlation studies will be accomplished. Although the main emphasis of contract will be to provide information about the dietary intake of children with high lead levels, the data will be compiled in such a manner as to provide information on food intake of children as influenced by social and economic factors as well.

Diet and Cadmium-Exposed Workers (PL-480): One hundred fifty industrial workers (100 exposed to cadmium, 50 unexposed) will be studied for a 24 month p (Text Truncated - Exceeds Capacity)

MICROBIAL CONTAMINATION AND PRESERVATION OF COSMETICS

J.P. Lucas, U.S. Dept. of Health & Human Services, Public Health Service, Food & Drug Admin., Bureau of Foods, *200 C St. S.W., Washington, District of Columbia* 20204 (10151)

STATEMENT OF OBJECTIVE: Develop laboratory testing methods and establish standards of performance, based on data obtained from comparative testing under conditions of use, suitable to determine the adequacy of protection of cosmetics against microbial contamination during manufacture and use by consumers. Investigate clinical cases of corneal ulceration associated with contaminated eye area cosmetics.

DESCRIPTION OF WORK: The contract study will be an extension of the work done by Wilson and Ahearn at Emory University, Atlanta, GA under contract #223-74-2016 which will terminate during the first quarter of FY 78. It will encompass a comparative study of several types of challenge tests (single, multiple, sequential challenges, etc.) on facial cosmetics containing various types of preservative systems and testing of the same cosmetics for microbial contamination under customary conditions of use. On the basis of the data obtained in these in-vitro and in-vivo tests, the challenge testing procedure which predicts most accurately the performance of a cosmetic under use conditions will be selected, and standards of performance which will assure adequate preservation under use conditions will be established for the selected challenge procedure. The laboratory work involving challenge testing will be supported by in-house efforts.

The clinical portion of contract #223-74-2016 will be continued to permit investigation of additional cases of corneal ulceration associated with eye area cosmetics.

2.0426,

IRON IN HUMAN NUTRITION

J.C. Fritz, U.S. Dept. of Health & Human Services, Public Health Service, Food & Drug Admin., Bureau of Foods, *200 C St. S.W., Washington, District of Columbia* 20204 (10208)

STATEMENT OF OBJECTIVE: To determine the quantitative need for dietary iron, and to determine how this is affected by other dietary components; to determine the extent of anemia among the United States population, and to identify those cases in which the anemia is due to lack of sufficicnt available iron in the diet; to select suitable foods to be fortified with iron, and to determine the feasibility of such iron fortification; and to identify suitable iron sources for such fortification.

DESCRIPTION OF WORK: These studies will be conducted under contract to the FDA, because FDA lacks clinical facilities of its own.

The purpose of Contract No.-223-73-2236, with Tulane University, is to study the efficacy of sources and levels of iron added to bread to meet the dietary needs of adult women and children. One group is receiving the usual commercial enriched bread with about 12.5 mg iron per pound with the iron furnished by FESO4, a second group is receiving similar white bread enriched to 25 mg iron per pound with the iron furnished by electrolytic iron, a third grup is receiving white bread enriched with ferrous sulfate to 25 mg iron per pound, and a fourth grgup is receiving white bread enriched to 75 mg iron per pound with ferrous sulfate. Various hematological parameters are being observed, including serum ferritin.

Contract No. 223-76-2112, with the Kansas Medical Center, was planned to develop a method which would measure iron storage in man. The serum ferritin method was compared with various other parameters of iron nutrition. This was done in an effort to establish a method, which could be applied in nutrition surveys, to evaluate iron status. Levels of serum ferritin below the normal level indicate iron deficiency, and values above the normal level indicate iron overload. Blood samples collected in the course of Northwest Nutrition Survey, HANES I, and HANES II were studied. Serum ferritin values were compared with othher hematological parameters on the same samples. Extensive inter-laboratory studies were made to standardize and validate the serum ferritin method.

Contract No. 05-001-0 was established with Lodz Medical Academy, under PL-480 provisions, to study the efficacy of iron fortification of floods to meet the dietary needs of adult women and of children. Preliminary studies were made to select suitable foods for fortification.

MERCURY CONTAMINATION IN FOODS

S.I. Shibko, U.S. Dept. of Health & Human Services, Public Health Service, Food & Drug Admin., Bureau of Foods, *200 C St. S.W., Washington, District of Columbia* 20204 (00011)

STATEMENT OF OBJECTIVE: Epidemiological Study of Outbreak of Methylmercury Poisoning in Iraq.

DESCRIPTION OF WORK: Contract U. Rochester: 1) Segmental analysis of hair samples obtained in Iraq, following the accidental poisoning episode, to provide additional information for dose/response studies. 2. Follow-up study of infant-mother pairs having exposure to methylmercury. 3. Prospective studies of the long-term effects of methylmercury.

Interagency agreement (DOE/FDA): Complete fabrication, testing and delivery to U. Rochester of the X-Ray Fluorescence Apparatus to analyze hair samples for mercury and other heavy metals.

Division of Toxicology: Review of literature relating to toxicity of methylmercury and other mercurials.

IN-DEPTH-REVIEW AND EVALUATION OF KEY PEDIATRIC PROBLEMS

J.G. Chopra, U.S. Dept. of Health & Human Services, Public Health Service, Food & Drug Admin., Bureau of Foods, *200 C St. S.W., Washington, District of Columbia* 20204 (09110)

STATEMENT OF OBJECTIVE: To obtain expert advice on specific pediatric nutrition problems which impact upon, or are affected by regulatory decisions.

DESCRIPTION OF WORK: The contractor will provide expert advice on specific pediatric nutrition problems which impact upon or are affected by regulatory decisions. the problems in question will be ones for which it is desired to: (a) develop guidelines for enrichment or fortification of foods for infant and preschool age children; (b) obtain suggestions, recommendations, and reinforcement relative to proposals and actions of the Bureau of Foods regarding pediatric nutrition problems and their solution; (c) review and analyze specific set of questions developed by the OADNICS for selected problem areas in pediatric nutrition of direct concern to the Agency; and (d) review (with necessary permission of sponsors) petitions related to pediatric topics submitted to the Agency for consideration.

Formal reports of state-of-the-art review and scientific interpretation of selected areas (three reports each year) are requested each year. In 1979 the reports on the following topics will be prepared: (1) Health Hazard from the overuse of Vitamin D; (2) Use of medium chain triglyceride in infant foods; (3) Effect of taste on Nutritional Status of Children.

LEAD CONTAMINATION IN FOOD

K.R. Mahaffey, U.S. Dept. of Health & Human Services, Public Health Service, Food & Drug Admin., Bureau of Foods, *200 C St. S.W., Washington, District of Columbia* 20204 (05356)

STATEMENT OF OBJECTIVE: To provide knowledge on the mechanisms of lead absorption and to determine what nutritional factors influence the absorption of lead and to determine the impact of high lead levels on the absorption and metabolism of essential nutrients.

DESCRIPTION OF WORK: The research in this project involves a series of studies on various factors known or suspected of affecting lead absorption and metabolism. An Interagency Agreement with the Center of Disease Control seeks to relate blood lead levels of various age groups with various hematological parameters. This information will provide baseline data on the status of the population and potentially indicate hematological relationships. Research will be continued under contract to identify dietary interrelationships such as lead and 1,25 (OH)2D3 and lead and calcium. The impact of these relationships in humans will also be investigated. A new effort will seek to determine the impact of calorie and/or protein deprivation on the mobilization of lead from body tissues. This research will attempt to assess the impact of negative calorie and protein balances which could occur during weight reduction, pregnancy or during times of severe illness. In-house efforts will be devoted to defining ascorbic acid in lead metabolism, the assessment of lead absorption from water and beverages having low levels of nutrients and assessment of the influence of age on lead distribution in body tissues.

NEOPLASMS IN IRRADIATED HUMAN POPULATIONS

E.D. Woodard, University of Rochester, School of Medicine & Dentistry, Dept. of Radiology, *601 Elmwood Ave., Rochester, New York* 14627 (5R01-FD-00634-15)

The long-term goal of this project is to determine the life-time risk of radiation-induced morbidity and mortality in three well-defined human populations treated many years ago for benign medical conditions (enlarged thymus gland, lymphoid hyperplasia of the nasopharynx, and acute post-partum mastitis). The observations of primary concern include cause-specific mortality, incidence of neoplasia, incidence of illnesses with abnormal immunologic features, and incidence of psychiatric illness.

Health data are collected by mail questionnaires from treated persons and from their untreated controls. Significant illnesses are verified by contacting the attending physician and/or hospital. Periodic screening by mammography and thermography of the breast-irradiated women and of eligible controls (NCI guidelines) is offered.

Histological sections of tumors of primary interest (thyroid, breast, and salivary gland) are reviewed. A comparison of the histopathology of breast cancers in breast-irradiated and in the control women is nearly completed.

CULTURAL FACTORS IN HYPERTENSION OF SPANISH-SPEAKERS

R.L. Ailinger, George Mason University, College of Professional Studies, Dept. of Nursing, *4400 University Dr., Fairfax, Virginia* 22030 (R01 NU 00624-02)

Hypertension is a mass public health problem in the U.S.; it afflicts twenty-three million people. Numerous studies have focused on the problem. However, there are no known studies of the epidemiology of hypertension in the Spanish-speaking population in this country. The proposed research examines the prevalence of high blood pressure in a Spanish-speaking population.

The literature suggests that acculturation has marked influences on the health status of individuals involved in culture change. But there is a dearth of reports in the nursing and medical literature on cultural factors in hypertension. The investigator will measure the association between acculturation level and prevalence of high blood pressure of respondents. She will describe their knowledge of hypertension and identify selected risk factors associated with it.

The research population will be selected from high density Spanish-speaking enclaves in Arlington County, Virginia. A systematic random sample of 330 households will be selected for hypertension screening and interviewing. The interview will be conducted in Spanish concerning acculturation, knowledge of hypertension, selected risk factors and demographic features.

It is anticipated that analysis of the data will produce new insight into hypertension in this rapidly emerging ethnic minority. The results of the study will contribute to the body of knowledge on acculturation and the nurses role in high blood pressure control.

BLOOD PRESSURE IN INFANTS OF TOXEMIC MOTHERS

J.S. Mausner, Medical College of Pennsylvania, School of Medicine, Dept. of Community & Preventive Medicine, *3300 Henry Ave., Philadelphia, Pennsylvania* 19129 (MCR-420399-03)

This project is designed to yield information on blood pressure of infants in relation to blood pressure of the mother, with particular interest in the offspring of women with toxemia of pregnancy. Women who meet specified criteria for pre-eclampsia or other hypertensive disorder are eligible for the study, as are normotensive women delivered at the same institution, matched for race and service (i.e., private vs. ward) who serve as a comparison group. Study subjects include both white and black women and represent private and service patients.

Blood pressure of the infant is measured by a Doppler ultrasound instrument (Arteriosonde) on the third day of life and subsequently at and 18 months of age. Where possible, infants born early in the period of enrollment will also be studied at 2 years.

ASSESSMENT OF THE IMPACT OF THE IPO PROJECT

D.M. Strobino, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Maternal & Child Health, *615 N. Wolfe St., Baltimore, Maryland* 21205 (MC-R-240421-02-0)

The objective of the study is to evaluate the impact of the Improved Pregnancy Outcome Project in two states, Mississippi and West Virginia, that are implementing the project on a regional or district basis. The Bureau of Community Health Services initiated this project in 1976 with the purpose of improving perinatal care and pregnancy outcomes in 13 states contributing excessively to the incidence of infant mortality in the U.S. A schema for the evaluation is developed using principles of evaluation including the use of control and treatment groups and investigation of alternative explanations for program effects. It is based on a social area analysis approach, using counties as the basic unit of analysis, and assumes that programs are implemented on a regional basis. the study period includes 3 years prior to implementation of the project and the 5 years of the project. Several diverse sources of data will be used including program data, general MCH and IPO activities, vital statistics data, census and intracensal data, general MCH and IPO activities, vital statistics data are the source of measures of the outcome of the project including several measures of pregnancy outcomes. Some vital statistics data will be used to control for changes in events other than the IPO Project, although census data will be the major source of data for these controls. Presence and absence of the program as well as program activities will be analyzed by county and region, controlling for concomitant variation. The analysis consists of several stages of progressively more sophisticated analyses including cross-tabulations, regression analysis and analysis of covariance.

A CONTROLLED EVALUATION OF REGIONAL PERINATAL CARE

E. Siegel, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Maternal & Child Health/Pediatrics, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514 (MC-R-370424-02-0)

The goal of the research is to design and carrout out a population-based evaluation to assure the impact of a regionalized perinatal care program in a rural North Carolina area. The major objectives are: (1) to determine how closely selected perinatal processes of care adhere to accepted standards in the study and control region, (2) to assess whether compliance to accepted standards of care influences perinatal short and long-term outcomes, and (3) to determine the impact of regionalized perinatal care on perinatal-mortality; postneonatal mortality; maternal and newborn morbidity; and physical, neurologic, developmental and maternal attachment status at 1 year conceptual age.

The process of care analysis will be accomplished by analyzing data from selected matched samples of mother-infant pairs in both the control and study regions through retrospective chart review. These same mother-infant pairs will be used to assess maternal and neonatal morbidity. Vital statistics data will be used to compare mortality and birthweight trends from 1947 through 1980 between the study and control region(s). One year outcome analysis will be carried out on samples of 250 survivors in both regions using a battery of interview and observation instruments to assess physical, neurologic, developmental, and maternal attachment status.

A COLLABORATIVE EPIDEMIOLOGICAL STUDY OF EPILEPSY IN INDIA

B. Ramamurthi, Madras Medical College, *Madras, Madras, India* (01-479-S)

SCOPE: A nationwide conference is under consideration to give the attendees some idea of the scope of the problem of epilepsy, the possibility of effective management, and the role of the Principal Investigator and his Institute in such activity.

A long-term prospective study of the frequency, distribution, and nature of epileptic seizures among patients in each of five hospitals. The institutions are uniquely capable of observing the particular effects of the socio-economic, cultural, religious, and emotional environment of each patient on the causes of seizures and the effectiveness of patient management. For example, the institutions will be able to observe seizure therapy as affected by religious beliefs which prescribe dietary restrictions.

This project is under a bilateral agreement.

EPIDEMIOLOGY OF ESSENTIAL HYPERTENSION AMONG VARIOUS ETHNIC GROUPS IN YUGOSLAVIA

V. Josipovic, Inst. of Chronic Diseases & Gerontology, *Slobodana Penezica 35/2, Belgrade, Yugoslavia* (02-125-S)

SCOPE: The primary goal of this project is to follow subjects identified as borderline hypertensives during its initial stages so as to determine the natural history of their disease. In addition, it will evaluate the effects of cultural and ethnic differences on the natural history of borderline hypertension. The ongoing case-controls epidemiological study has assessed 9,600 subjects (divided into normotensive, hypertensive and borderline groups) on the basis of explicity defined criteria. Division into six ethnic groups, two age groups, (30-45 and 45-60 years), two sexes, and two places of residence (rural or urban) will provide approximately 200 subjects in each of the resulting 48 cells with a total of 9,600 subjects. The situation in Yugoslavia provides a unique opportunity to follow this group of subjects where nothing is known about their natural history.

Extensive epidemiological surveys have been conducted in the United States on hypertension and hypertensive heart disease in adults. It is estimated that twenty-four million Americans have hypertension with only one-half identified, and three million controlled with adequate therapy. In particular, the U.S. Public Health Service Cooperative Studies on Hypertension and Renal Disease has conducted an evaluation of the effect of treatment on morbidity and mortality in mild to moderate essential hypertension. Because one of the outcomes of the project will be an analysis of the role of borderline hypertension and pulse rate as a predictor of essential hypertension, it will contribute significantly to the understanding and management of this disease, prevalent in practically all nations.

EPIDEMIOLOGY, NATURAL HISTORY, AND CONTROL OF TRACHOMA IN TUNISIA

T. Daghfous, Institut dOphthalmologie, *Tunis, Tunisia* (07-075-S)

OBJECTIVE: Project is aimed at developing better methods to prevent blindness and visual loss in trachoma. It is concerned with infectious eye diseases, particularly trachoma. Main thrust of the studies will be aimed at the rural population and will be particularly concerned with preventing blindness complications in children under the age of 10. Studies will also be carried out on infections of the eye with herpes simplex virus infections of the eye which often have chronic and recurrent occurrences. Thus it is intended to study the natural history of this disease so as to determine the best methods of treatment and prevention.

CHRONIC SEQUELAE OF NON-A, NON-B HEPATITIS

J. Hoofnagle, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, Clinical Center, Immunology Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CL 02010-05 BB)

All patients developing non-A, non-B hepatitis following open heart surgery will be followed with serial studies of SGPT to determine the incidence of chronic liver disease and to compare this incidence with those having type B hepatitis. Liver biopsy will be obtained when the SGPT is elevated for more than 6 months and then again at one and three years. Biopsy material will be obtained for fluorescent and EM studies, as well as light microscopy with multiple stains.

EVALUATION OF ANTI-CORE ANTIBODY AND SERUM TRANSAMINASE AS INDICATORS OF THE INFECTIVITY OF HBSAG-NEGATIVE DONORS

H.J. Alter, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, Clinical Center, Immunology Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CL 02016-02 BB)

Despite sensitive radioimmunoassay tests for HBsAg applied to all donor blood, some type B hepatitis continues to occur following transfusion. It has previously been suggested that HBsAg negative individuals who have anti-core antibody may transmit the hepatitis B virus. The availability of a new sensitive radioimmunoassay for anti-core antibody allows this postulate to be tested in our prospectively followed, open heart surgery patients. Similarly, we can ascertain if chronic carriers of non-A, non-B hepatitis have elevated serum transaminase; and, if so, whether

this could be employed to screen donors and reduce the frequency of post-transfusion hepatitis due to this agent.

PROSPECTIVE STUDY OF POST-TRANSFUSION HEPATITIS IN OPEN HEART SURGERY PATIENTS
H.J. Alter, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, Clinical Center, Immunology Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CL 02005-10 BB)
To prospectively follow all adult patients undergoing open heart surgery for the development of post-transfusion hepatitis and by appropriate serologic tests to determine the causative agents. Primarily interested in investigating the incidence of 'non-A, non-B' hepatitis and to see if there are any epidemiologic or serologic clues to its prevention. This study will also compare the clinical course of the various forms of PTH and determine the frequency with which chronic hepatitis develops.

THE DUFFY BLOOD GROUP DETERMINANT AND SUSCEPTIBILITY TO MALARIA
L.H. Miller, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, Clinical Center, Immunology Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CL 02011-05 BB)
Working with an in vitro model for invasion of red cells by malaria merozoites, this study has demonstrated that human red cells lacking the Duffy a and b antigens are resistant to invasion. This corresponds well with epidemiologic studies which show that approximately 70% of West African and American blacks are resistant to Vivax malaria. A similar proportion of these blacks are Duffy a and b negative whereas the Duffy negative genotype is extremely rare in other racial groups. The close association between the Duffy negative genotype and resistance to Vivax malaria has also been confirmed by retrospective analysis of 11 volunteers experimentally inoculated with P. vivax. A retrospective study of U.S. servicemen who contracted malaria in South East Asia has been completed and confirmed again our original hypothesis. A second study conducted by CDC in Honduras has also been completed and is another in-vivo study in-proof.

STATISTICAL RESEARCH IN CLINICAL PATHOLOGY
E.K. Harris, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, Div. of Computer Research & Technology, Laboratory of Applied Studies, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CT 00007-11 LAS)
In cooperation with Dr. G.Z. Williams and staff of the Health Research Institute (San Francisco), records of some 30 different biochemical and hematological tests performed annually over a 4-7 year period on several hundred healthy volunteers have been analyzed to test the adequacy and usefulness of 3 statistical forecasting models described in previous reports and publications. An initial report of this work is in preparation. The theory of Empirical Bayesian estimation has been explored to determine its usefulness as a way of improving estimates of individual mean values of biochemical constituents. Initially, applications to epidemiological studies have been investigated (Ref. 1). Work currently in progress tests the application of this theory to patient data from hospital laboratories. Another cooperative study examines the distribution of within-person variance in healthy volunteers and its effects on reference ranges and other medical diagnostic criteria. Finally, joint studies with cooperating pathologists have begun on the power of various statistical models and tests to detect short-term trends in biochemical quantities.

W.H. Luginbuhl, University of Vermont & State Agricultural College, School of Medicine, Dept. of Pathology, *85 S. Prospect St., Burlington, Vermont* 05401 (M01 RR 00109-16)

The Clinical Research Center at the University of Vermont consists of a six-bed research ward including a special diet kitchen, core laboratory and special procedure rooms which provide inpatient and limited outpatient facilities for the conduct of original investigation by members of the medical faculty. It is staffed by full-time nursing, dietary and laboratory personnel who are highly trained in patient care and research techniques. Thus, the Center provides an environment where suitable patients may be studied under optimum conditions for experimental control and accurate data collection.

Proposed research projects must be approved by the Committee on Human Experimentation for the Medical Science and are subjected to critical review by the Program Director and CRC Advisory Committee prior to final approval. They are rated on the basis of scientific merit, methodology and appropriateness for human investigation. A priority rating is established for each research project and admission of patients to the Center is determined accordingly.

The Clinical Research Center serves multiple subspecialty disciplines in the medical center. Current areas of interest include: 1. Overfeeding and Experimental Obesity in Man. 2. Absorptive Defects and Immune Mechanisms in Regional Enteritis. 3. Diffuse Interstitial Lung Disease. 4. Effects of Over- and Undernutrition on Thyroid Hormone Physiology. 5. Nutritional Assessment and Energy Balance of Hospitalized Patients with Anorexia nervosa, Malignancy, and other Chronic Diseases. 6. Multiple Sclerosis.

W.B. Deal, State University System of Florida, University of Florida, School of Medicine, Dept. of Medicine, *1600 Archer Rd., Box J-266, Gainesville, Florida* 32610 (M01 RR 00082-17)

This 7-bed unit, in operation since 1962, continues to function at a high level of activity with over 40 active protocols involving many collaborative efforts with members of the departments of medicine, pediatrics, surgery, neurology, psychiatry, ophthalmology, radiology, and obstetrics/gynecology of the College of Medicine, College of Pharmacy, Nursing and Health Related Professions. Current studies include investigation of Vitamin B12 absorption mechanism and blind loop syndrome with new diagnostic techniques including breath and pharmaceutical tests to describe pancreatic insufficiency; visual function and zinc deficiencies as related to malabsorption problems; alteration in biologic mineralization including renal stone formation and prevention, hyperparathyroidism and rickets and alteration of thyroid function studies from iodination of the water supply; multiple and collaborative in-depth investigations of patients who have undergone bypass surgery; the body's metabolism and disposal of a variety of drugs in the treatment of epilepsy; gastric ulcer studies of absorption of drugs in malabsorption situations; oncology studies; the natural history of diabetes mellitus and relationship between metabolic and vascular problems in diabetes; investigations of new pathways of metabolism; insulin receptor binding studies; salivary insulin secretion; mechanisms and treatment of sexual precocity; intestinal perfusion studies, gastrin secretion, electrolyte balance in athletes and nutritional studies.

GENERAL CLINICAL RESEARCH CENTER - ADULT AND CHILDREN

A. Ebbert, Yale University, School of Medicine, Dept. of Internal Medicine, *333 Cedar St., New Haven, Connecticut* 06510 (M01 RR 00125-16)

The objective of this grant is to support the Clinical Research Center at the Yale-New Haven Medical Center, Inc. and Yale University School of Medicine. The Center permits the full-time staff and their postgraduate fellows to conduct clinical investigation in order to obtain a better understanding of the mechanisms of disease. Therapeutic measures are developed or tested in this Unit. In addition, it is most valuable to the medical education and training of the future practitioners and faculty members.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, Div. of Research Resources $1,206,919

2.0475,

GENERAL CLINICAL RESEARCH CENTER (MATERNAL-CHILD)

F.C. Robbins, Case Western Reserve University, School of Medicine, Dept. of Medicine, *2109 Adelbert Rd., Cleveland, Ohio* 44106 (M01 RR 00210-15)

The PCRC is an environment providing support for clinical research programs, involving mother, fetus and neonate, as well as a setting for educational programs. Such programs at the Doctoral, postgraduate medical and post-residency fellowship (Maternal-Fetal Medicine and Neonatology) levels continue to be active in the Center. To extend our educational efforts, in this Application we are requesting a Clinical Associate Physician (CAP) position for a qualified junior investigator, who has completed his Maternal-Fetal Medicine fellowship training, to continue the development of his research expertise, while simultaneously supplementing professional care for Center patients. The CAP will be directly supervised by the PCRC Program and Assistant Program Directors and the Co-director for Engineering. The proposed study is summarized below.

Electronic monitoring before and during labor is used for detecting fetal distress; the sensitivity and specificity of these techniques are limited. Our experience with antepartum electronic fetal monitoring over a three year period in the PCRC has led to the description of new methods in fetal evaluation as reflected by the fetal heart rate, fetal movements and fetal respiratory activity. These same interrelated physiologic variables have been described in the newborn in sleeping and waking periods as behavioral states. In the neonate, these states reflect maturation and development of the human brain and have

been found to be altered in instances of abnormal growth, such as the small-for gestational age infant and the infant of the diabetic mother. We hypothesize that the organization of active and quiet periods begins in utero, that this can be quantitated and described statistically and that detectable alterations in the organization of these periods before birth will provide a useful method for the earlier identification of the sick fetus.

Moreover, Dr. Dierker, the CAP Applicant, has been one of the senior investigators in the study of one of these variables, fetal respiratory movement. This continuing program will allow him to more clearly describe the ontogeny of fetal respiratory movement and its relationships after birth.

GENERAL CLINICAL RESEARCH CENTER

M.R. Grover, Oregon State Higher Education System, University of Oregon Health Sciences Center, School of Medicine, Dept. of Surgery, *3181 S.W. Sam Jackson Park Rd., Portland, Oregon* 97201 (M01 RR 00334-13)

The Clinical Research Center at the University of Oregon Health Sciences Center is currently conducting human research across a wide number of human disease states as well as numerous physiologic and pharmacologic observations on normal volunteers. Subjects under active investigation at the present time include: (1) solid tumor chemotherapy, (2) progesterone, prolactin and estrogen interaction and manifestations in metastatic breast carcinoma, (3) hyperlipidemia and cholesterol metabolism, (4) Raynaud's syndrome and other vasospastic diseases, (5) autoimmune diseases, (6) bronchial asthma, (7) effect of methadone on respiration, (8) investigations of new diuretic agents, (9) studies on growth hormone, (10) agammaglobulinemia, (11) hyperlipidemia of renal disease, (12) evaluation of floctafenine, (13) blood pressure control, (14) parathormone secretion in end-stage renal disease and parathyroid secretory function after parathyroidectomy, and (15) evaluation of hypersecreting pituitary tumors.

BIOMEDICAL SCIENCES

J.K. McNeley, Navajo Community College, Undergraduate School, Dept. of Social Sciences, *Tsaile, Arizona* 86556 (S06 RR 08163-02)

The program involves Navajo Community College students in research on significant health problems among the Navajo population. The Navajo Drinking Behavior project, having arrived at a cultural definition of alcohol abuse through the use of ethnoscience ethnographic procedures, will investigate the incidence of alcohol abuse of a sample of the Navajo population through the use of social survey research techniques. Clinical applications of research findings will also be explored. The Gastroenteritis project is investigating the incidence of diarrhea among newborn lambs and young children on the Navajo reservation with the objectives of identifying the agent(s) causing diarrhea within the two target populations as well as the environmental factors contributing to diarrhea. The Streptococcal Diseases project is engaging students in the isolation of beta-hemolytic streptococci from clinical sources and identification through presumptive grouping of A strain by bacitracin sensitivity and B strain by the cAMP test and hippurate hydrolysis followed by verification of presumptive grouping results by the fluorescent anti-body technique.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, Div. of Research Resources $128,900

2.0486,

GENERAL CLINICAL RESEARCH CENTER

T.E. Gaffney, Medical University of South Carolina, School of Medicine, Dept. of Pharmacology, *80 Barre St., Charleston, South Carolina* 29401 (M01 RR 01070-03)

This is a continuation of our proposal for NIH support of our seven-bed General Clinical Research Center at the Medical University of South Carolina. This unit is utilized for both adult and pediatric patients. Areas of study will again include: platelet aggregation abnormalities in diabetes mellitus; vasoactive abnormalities in acute myocardial infarction and unstable angina; the pathophysiology of prostaglandins in renal physiology and disease; the role of sodium in the pathogenesis of pre-eclampsia; collagen metabolism in connective tissue disease; the kallikrein-kinin system in hypertention; the role of hypoxia in pulmonary hypertension; calcium metabolism in bone, fibroblast and other disorders; the sympathetic nervous system and arterial pressure control mechanisms; ascorbic acid therapy for dyskinesias; central hypotensive mechanisms of alpha methyldopa; the mechanism of action and disposition of propranolol; the mechanism of action and disposal of varied drugs used in the control of hypertension, and the control of prolactin.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, Div. of Research Resources $409,762

2.0487,

SUPPORT FOR STUDY OF BIOMEDICAL SCIENCES

J.M. Verrett, Dillard University, Undergraduate School, Dept. of Biology, *New Orleans, Louisiana* 70122 (S06 RR 08064-09)

The research program is designed to increase research training capability and experimental productivity in the Natural Sciences Division at Dillard. Three individual research problems involving three (3) faculty members and eleven (11) students will be studied as follows: (1) Water Balance in the American Cockroach - a project designed to determine how the frontal ganglion keeps the body fluids of the cockroach in a homeostatic state; (2) Skin Testing Program - to develop an antigen useful in skin testing to study the epidemiology of Sporothrix schenckii, and to isolate spores from soil to study the ecology of the fungus; and (3) Characterization of Corneal Mucoproteins - to extract and fractionate corneal acidic polysaccharides, chondroitin-4-sulfate and keratan sulfate and ascertain the hydration of each fraction.

2.0488,

BIOMEDICAL, CLINICAL MASS SPECTROMETRY RESOURCE

A.L. Burlingame, University of California, Berkeley Campus, Space Sciences Lab., *3 Leuschner Observatory, Berkeley, California* 94704 (P41 RR 00719-03S2)

This proposal seeks continued pilot-level support for a biomedical-clinical mass spectrometry research resource for the San Francisco Bay area which would effectively service northern California by virtue of collaborative liaison with clinicians--routinely treating patients in this entire geographical area.

It is the expressed purpose of this program to spearhead West Coast exploration of the scope and exploitation of the applications of existing know-how and continually upgraded analytical capabilities of computerized mass spectrometry (both high and low

resolution, gas chromatography/high resolution mass spectrometry, chemical ionization, field desorption) and related separation techniques to problem areas of importance to the clinicians of the San Francisco Bay area.

The ingredients which are necessary in order to implement the program as envisaged include: 1) mobilization and utilization of core of expertise in existing mass spectrometry group and its augmentation with added biomedically oriented personnel; 2) upgrading of existing mass spectrometry and computer software capability and its tailoring to tractable medical priorities set by advisory committee and Principal Investigator; 3) implementation of a routine mass spectrometry service and accessible interpretative expertise for collaborating clinicians and clinical pathology laboratories; and 4) active program in the dissemination of knowledge of scope and extent of center analytical capabilities into the clinical and biomedical community through an elective medical scientist and M.D. training program.

Some of the areas of clinical importance which are being investigated include the study of genetic diseases, the screening of potentially mentally retarded children, screening for inborn errors in metabolism, the detection of cancer prior to clinical symptoms, appraisal of metabolic profiles in physiological fluids and tissue, etc. The use of mass spectrometry emergency diagnosis in drug and toxin overdose cases is of great interest.

2.0489,

GENERAL CLINICAL RESEARCH CENTER

R.L. Van Citters, University of Washington, School of Medicine, Dept. of Medicine, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (M01 RR 00037-19)

The Clinical Research Center at the University Hospital was activated in 1960 and has been maintained through support by the National Institutes of Health. This multidisciplinary facility provides a milieu for the conducting of clinical research encompassing a broad spectrum of human physiopathology and disease. The specific purposes are to provide an environment for investigation of human physiology in health and disease under carefully monitored conditions and to provide optimal medical supervision and protection of the human subjects' rights and welfare. This facility also enables the study of unusual diseases or unique opportunities to study commonly encountered clinical disorders under conditions or supervision which could not be readily obtained in primary clinical care facilities. The Center also constitutes a place where postgraduate and undergraduate students in medicine, nursing, and diabetics can obtain in-service experience in clinical research under established investigators.

BIOLOGICAL, BIOCHEMICAL, BIOPHYSICAL STUDIES

S.P. Sood, University of Hawaii System, Manoa Campus, School of Arts & Sciences, Dept. of Chemistry, *2444 Dole St., Honolulu, Hawaii* 96822 (S06 RR 08073-09)

This proposal encompasses a wide spectrum of projects of Biological, Biochemical, Biophysical, Behavioral, Environmental and Cancer Studies with a common theme of biomedical relevance. The projects are so conceived as to allow a meaningful and productive training and research of minority undergraduate student participants.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, Div. of Research Resources $23,800

2.0491,

BIOCHEMICAL AND PHARMACOLOGICAL INVESTIGATIONS

L.P. Tserlikkis, State University System of Florida, Florida Agricultural & Mechanical University, School of Pharmacy, Dept. of Pharmaceutics, *Tallahassee, Florida* 32307 (S06 RR 08111-08)

The overall objective of the program is to establish a bonafide investigation in biochemical and pharmacological aspects of biomedical research. The proposed research program will encompass studies from subcellular to organism level, since any pharmacological response is caused by various biochemical and physiological contributing factors. The response might be due to an agent or to an environmental stress; thus, one must monitor several interlocking aspects of the biochemical factors involved. The projects are all involved in directly monitoring the following factors: (a) cytological changes of various animal organs due to the deficiency of Vitamin B6 with respect to the role of pyridoxal phosphate and also several kinetic properties, (b) investigation delineating physiological and pharmacological conditions through corticosteroid metabolism which produces acidic metabolites and will be monitored by mass-fragmentographic technique, (c) optimization of the therapeutic index of cancer chemotherapeutic agents through cell kinetic and pharmacokinetic approaches and (d) synthesizing of various ketodeoxyhexosyl uracils and determining the structural activity of these synthetic potential cancer agents.

OUT-PATIENT CLINICAL RESEARCH CENTER

R.S. Ross, Johns Hopkins University, School of Medicine, Dept. of Medicine, *725 N. Wolfe St., Baltimore, Maryland* 21205 (M01 RR 00722-07)

Partial support is proposed for a special facility for ambulatory clinical investigation through The Johns Hopkins Out-patient Department-Clinical Research Center. Based on a 16-year previous experience of long-term out-patient investigation in a large number of disorders the proposed Center will provide facilities and financing for continual studies in acute and chronic medical surgical illnesses of potential significance, the nature of which precludes in-patient investigation and for which clinical research can be most effectively and economically conducted on ambulatory subjects. Patients of all age groups will be included. Special resources contributing to the understanding of such diseases will include biomathematics, epidemiologic, and clinical pharmacologic units. A volume of 10,000 patient-visits per year is anticipated.

From among research protocols covering a wide variety of disciplines representing essentially all departments of the Medical School a standing Clinical Research Center Committee will select and approve specific investigations. Administrative organization, financial aspects of support for patient visits and ancillary services, personnel and staffing, specialty units, and required renovation have been presented in the original application. Of special interest are the use of case assistants and development of a records system with computer-based methods for storing and analyzing research data.

GENERAL CLINICAL RESEARCH CENTER

T. Cooper, Cornell University, Medical Center, Cornell Medical College, Dept. of Medicine, *1300 York Ave., New York, New York* 10021 (M01 RR 00047-19)

The objective of the General Clinical Research Center at The New York Hospital-Cornell Medical Center is to maintain and operate a multidepartmental and multicategorical research center for the study of disease mechanisms in man under controlled conditions of environment, collection of samples, and methods of medical care. The Clinical Research Center will be utilized by the several clinical departments of Cornell University Medical College and, when applicable, combined studies will be carried out with preclinical departments. The Center is housed within geographically separate, essentially autonomous clinical research areas (an eight bed adult unit, a six bed pediatric unit, supporting core laboratories, and other ancillary space), and is staffed by a complement of physicians, nurses, dieticians, technicians, and other personnel necessary to provide the Cornell Medical Center with integrated units for meritorious clinical investigation of the institution's own choosing.

GENERAL CLINICAL RESEARCH CENTER

D.M. Kipnis, Washington University, School of Medicine, Dept. of Medicine, *660 S. Euclid Ave., St. Louis, Missouri* 63110 (M01 RR 00036-19)

The Washington University Clinical Research Center has now been in operation for 12 years and consists

of a 25-bed adult unit and an 8-bed pediatric facility operated as independent nursing services but functioning under a single administration and sharing dietary and core laboratory resources. Both the adult and pediatric units are designed so that the acutely ill as well as the ambulatory patient and normal volunteer can be studied. The Center provides for the hospitalization of patients in a setting in which expert dietary control, skillful intensive nursing care and facilities for specialized studies can be performed. The Clinical Research Center Core Laboratories provide assistance for specialized determinations used by multiple investigations and represents a research resource for the development of new analytical procedures. All faculty members of the clinical and basic science departments of the Washington University School of Medicine who wish to pursue clinical investigation and have research protocols approved by the University Committee on Human Experimentation and by the Advisory Committee of the Clinical Research Center may use the resources of the Center. Although the major function of the Clinical Research Center is clinical investigation, it also provides opportunities for undergraduate and postgraduate training in clinical investigation.

GENERAL CLINICAL RESEARCH CENTER

H.C. Knowles, University of Cincinnati, School of Medicine, Dept. of Internal Medicine, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221 (M01 RR 00068-17)

The clinical Research Center is involved in the following major active projects from among 123 active protocols: 1. Lipo- and apo-lipoprotein metabolism: Studies focused on diet and drug therapy of familial dyslipoproteinemias, pediatric precursors of atherosclerosis, genetics of dyslipoproteinemia, apo-lipoproteins, and triglyceride catabolism. 2. Diabetes and pregnancy: A prospective study of the effect of maternal diabetic control on fetal morbidity, mortality, and congenital malformations is being carried out. 3. Cholesterol lowering compounds: The cholesterol and LDL cholesterol lowering effects of a non-absorbable synthetic fat, Sucrose Polyester, are being assessed. Cholesterol balance studies are being carried out. 4. Diabetes and renal transplantation in end-stage diabetic renal disease: Metabolic studies pre- and post-dialysis and renal transplantation in diabetics with end-stage renal disease are being carried out. 5. Nephrotic syndrome: A study of HDL and Apo CII lipoproteinuria and their relationship to lipoproteinemia of nephrotic syndrome is being carried out. 6. Care of infants in high risk pregnancies: This study is designed to study infants born to diabetic mothers and mothers whose metabolic diseases make pregnancy high risk. These infants room in with the mothers and are monitored closely by plasma and urine specimens. 7. A correlation of tubular function and morphology in lupus nephritis: Studies of renal tubular functions in patients with lupus nephritis. 8. Study of growth and development in children: Relationship of infantile nutrition and growth in the 1st yr of life to subsequent obesity, lipoprotein status and mental acuity.

GENERAL CLINICAL RESEARCH CENTER (CHILDREN)

B.C. Paton, University of Colorado, Medical Center, School of Medicine, Dept. of Pediatrics, *4200 E. 9th Ave., Denver, Colorado* 80262 (M01 RR 00069-17)

The Children's General Clinical Research Center at the University of Colorado Medical Center is a 6-bed facility designed to provide hospitalization with superior nursing and laboratory support for the investigation of disease in childhood. In the last year there has been a significant change in many aspects of the research conducted. The Children's GCRC now has the largest group of infants with biliary atresia, outside of Japan, on which the Kasai procedure has been carried out. The utilization of the Center for the evaluation of new metabolic disease has increased with cases of glyceroluria and glutaric aciduria. Bone marrow transplants are being attempted again in children with aplastic anemia and certain immune deficiency diseases.

At the same time, long standing studies on essential fatty acids and prostaglandins in cystic fibrosis and on trace metal disorders continue vigorously. There is, in addition, an active outpatient effort, and the Core Laboratory continues its essential supportive role.

PROSTATIC CANCER - GENETIC AND ENDOCRINE RISK FACTORS

A.W. Meikle, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Internal Medicine, *1400 E. 2nd S., Salt Lake City, Utah* 84112 (R26 CA 25031-02)

Our major goal is to determine the role of genetic factors in the development of prostatic cancer. Our hypothesis is that genetic factors affect secretion of sex-hormones and prolactin and predispose men to the early development of prostatic cancer in response to endogenous hormones and environmental carcinogens. Our probands will be less than 61 years of age when the diagnosis of prostatic cancer is made. We will determine whether (1) the plasma concentrations of sex steroids (estradiol-17beta, estrone, testosterone and dihydrotestosterone) and prolactin are abnormal in probands and first-order relatives as compared to age-matched in-law controls and whether the plasma concentrations of the hormone are affected by heredity; (2) the risk of the development of prostatic cancer is higher in first-order relatives and maternal and paternal relatives of the index cases than in age-matched controls; (3) the prevalence of some apparent epidemiologic risk variables are observed more commonly in probands and their first-order relatives as compared to age-matched controls. The investigation is novel in that the hereditary, endocrine and epidemiologic risk variables for the development of prostatic cancer will be investigated in younger men with the cancer and their relatives.

The investigation is feasible because of the availability of a population with large families and a high incidence of prostatic cancer.

EXPLORATORY STUDIES OF CANCER PATIENT DATA CONTROL

S.J. Cutler, Georgetown University, School of Medicine, Dept. of Community & Family Medicine, *3800 Reservoir Rd. N.W., Washington, District of Columbia* 20007 (R10 CA 25146-02)

This application provides for support to enable the Epidemiology and Statistics Unit of the Georgetown University component of the Georgetown University-Howard University Comprehensive Cancer Center (the Vincent T. Lombardi Cancer Research Center), under the direction of Sidney J. Cutler, Sc.D., Professor, Department of Community and Family Medicine, to further develop and maintain an effective computerized cancer information system and epidemiologic research program. The system, using codes, definitions, and procedures compatible with the Centralized Cancer Patient Data System, will help promote active collaboration between Georgetown University and Howard University and will be the basis for the development of a community-oriented epidemiological research program. Data on more than 800 new cancer patients plus information on an additional 2500 active cases are entered into the data base and utilized for analyses of patient characteristics, treatment and its end-results, and other descriptive reports. These analyses should provide clues on trends and patterns which warrant special studies, and any pertinent data will provide Georgetown Medical Center committees and the Cancer Coordinating Council of Metropolitan Washington means for implementing or changing cancer control programs or medical care policies.

COLORECTAL CANCER AMONG CALIFORNIA MORMONS

L. Breslow, University of California, Los Angeles Campus, School of Public Health, Health Service & Hospital Administration, *405 Hilgard Ave., Los Angeles, California* 90024 (R26 CA 25157-01)

Based on our analysis of Church records, religiously active Mormon males in California and Utah compared with U.S. white males have standardized mortality ratio of 60% for colon cancer, 40% for rectum cancer, and 55% for colorectal cancer. Active Mormons abstain from tobacco, alcohol, and caffeine by Church prescription. However, the specific reasons for their low colorectal cancer rates are unknown.

The first objective is to pursue this descriptive mortality data with a prospective epidemiologic study of active California Mormon adults of both sexes. Using a questionnaire survey, demographic, lifestyle, dietary, occupational, and medical history data relevant to colorectal cancer etiology will be obtained on about 20,000 active Mormons, who will subsequently be followed for mortality over a four-year period. Furthermore, Church-based mortality rates covering the years 1960-67 and 1976-79 will be ascertained for all 350,000 California Mormons in order to supplement the existing rates for the years 1968-75. The questionnaire data on dietary and other lifestyle characteristics will be related to the colorectal cancer mortality rates. In addition to intra-Mormon comparisons, active Mormons as a whole will be compared with other California, U.S., and international populations which already have been studied with respect to colorectal cancer.

The second objective is to do a correlation analysis of extensive dietary and lifestyle data from the 1971-73 U.S. Health and Nutrition Examination Survey (HANES) with U.S. and California colorectal cancer mortality rates by country of birth and state of residence. Several etiologic variables of interest, including beef, fat, fiber, and beer consumption, will be examined for consistency with international correlations and previous epidemiologic findings. Special emphasis will focus on Spanish Americans born in Mexico, who have colorectal cancer death rates as low as those of active Mormons. The above analy-

ses should yield new understanding of the etiology and prevention of large bowel cancer in the United States.

REGRESSION ANALYSIS TECHNIQUES FOR CANCER RESEARCH

D.A. Schoenfeld, Sidney Farber Cancer Center Inc., *44 Binney St., Boston, Massachusetts* 02115 (R23 CA 25162-01)

The paper 'Regression Models and Life Tables' published by D.R. Cox in 1972 introduced an important new statistical methodology that has considerable application to cancer research. It provides a method for determining the effect of explanatory variables, such as patient characteristics, on survival. The object of this reseach is to develop supplementary statistical methodologies. In particular, methods will be developed to examine goodness-of-fit, measure strength of prediction, select variables from a large set, account for missing data, model random effects and perform small sample permutation tests. These methods have been developed for the usual 'Least Squares Regression' and have been invaluable in areas of scientific research. The analogous methods for life table regression will put important new statistical tools in the hands of clinical researchers and biostatisticians. the necessary computer software will be developed so that the new methodologies can be used by other investigators.

MONITORING FOR CANCER RISKS

J.W. Berg, Colorado Regional Cancer Center Inc., Division of Epidemiology & Statistics, *1655 Lafayette St., Suite 301, Denver, Colorado* 80218 (R18 CA 25254-02)

The ultimate objective is to identify environmental causes producing new increases in cancer risk among residents of the area served by the Colorado Regional Cancer Center. The focus will be on increases of previously rare cancers since large relative increases should be visible even with only early (i.e., incomplete) case ascertainment. A computer program will be created to analyze the monthly-updated tape file of the Colorado Central Cancer Registry for increases in cancers of unusual histology or in patient groups in which the cancers had been uncommon. Entities showing a suspicious increase will be selected for two kinds of interview investigation: follow-back on cases already in the Registry files and interviews of new patients as they are admitted to regional hospitals.

CANCER CONTROL DEVELOPMENT - CINCINNATI STRATEGY

C.R. Buncher, Childrens Hospital Medical Center, Cincinnati Cancer Control Program, *3245 Burnet Ave., Cincinnati, Ohio* 45229 (R18 CA 25299-01)

The Cancer Control Support and Demonstration effort represents a community-wide program to impact Cincinnati's higher mortality rate and lower level of organized cancer management treatment and service resources. The proposal requests funds to: (1) geographically map cancer in Cincinnati, (2) plan community resources, (3) develop a comprehensive occupational/industrial worker education and survey program and (4) a program to develop basic treatment capabilities within the medical community.

This will be accomplished with a small core staff, a broad base of community nurses and hospital administrators and specialist expertise such as that within Cincinnati's Kettering Laboratory.

2.0510,

HEPATOCELLULAR CARCINOMA RISK IN HEPATITIS B CARRIERS

R.P. Beasley, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105 (R01 CA 25327-01)

This study is designed to determine: 1) Incidence and relative risk of primary hepatocellular carcinoma (PHC) among hepatitis B virus (HV) carriers compared to non-carriers, and 2) whether alpha-fetoprotein (AFP) can be used as a practical screening method for early PHC detection. The population cohort is 20,000 male Chinese government employees in Taiwan age 40-59 who have mandatory health and life insurance which assures medical care for illness and detection of disease. HBV carriers constitute 15 percent of this population and are at increased risk of developing PHC, the leading malignant neoplasm in Taiwan. HBV carriers and a matched cohort of non-carriers are tested yearly for HBV markers to determine changes in infection status and for AFP (radioimmunoassay) to detect preclinical PHC.

2.0511,

CERVICAL CANCER EPIDEMIOLOGY IN PANAMA

W.C. Reeves, Gorgas Memorial Inst. of Tropical & Preventive Medicine Inc., Dept. of Virology, *2007 I St. N.W., Washington, District of Columbia* 20006 (R01 CA 25419-01)

In this application we propose to evaluate an unusually high uterine cervical cancer incidence in the Republic of Panama. Panama not only has the highest reported cervical cancer incidence in the world but also demonstrates geographic clustering and a marked shift in age specific incidence (most invasive cervical cancer occurs in 20-39 year old women). We plan to evaluate this by first recording all cervical cancer cases which occurred between 1974-1977, in a standardized national cancer registry. We will then do a seroepidemiologic case-control study comparing socioeconomic, sexual and herpes group virus risk factors in cases and controls. In addition we plan to measure other variables which might account for the unique aspects of cervical cancer seen in Panama. Lastly we will evaluate the effects of the existing Pap smear program and collaborate in initiation of a more intensive screening program.

2.0512,

STUDY OF MALES EXPOSED IN UTERO TO DIETHYLSTILBESTROL

L.T. Kurland, Mayo Foundation, Dept. of Medical Statistics & Epidemiology, *200 1st St. S.W., Rochester, Minnesota* 55901 (R01 CA 25441-02)

DES (diethylstilbestrol) has been shown, in studies of animals and on a small scale in humans, to be associated with genitourinary abnormalities and possible reduced fertility in males exposed to the drug in utero. Human studies to date do not demonstrate an association with cancer in the DES-exposed male. However, preliminary reports of case control studies in progress have suggested such an association. Whether the exposed young men will have an increased propensity to develop cancer at a later date remains speculative.

The proposed study is primarily designed to determine if DES-exposed males are at a higher risk of genitourinary problems or infertility than non-exposed males. This would be accomplished by identifying and examining a cohort of 700 DES-exposed and 700 non-exposed males and by a follow-up over a 2-year period. The DES-exposed males will be identified through the cooperative efforts of three institutions currently collecting data for the DESAD Project (the study of DES-exposed females): Baylor College of Medicine, Mayo Clinic, and the University of Southern California. The young men will be examined for clinical abnormalities and variations in levels of FSH, LH and testosterone. It is expected that the study will provide further information regarding the prevalence of abnormalities in DES-exposed males - information relating to the role of DES in teratogenesis and the public health aspects of the problem. Ultimately, this study should lead to greatly increased accuracy of assessment of the health status of the DES-exposed men and to recommendations regarding their long-term surveillance (and health care, if needed).

CANCER IN WOMEN RECEIVING EXOGENOUS ESTROGENS

M. Arnold, Colorado Regional Cancer Center Inc., *1655 Lafayette St., Suite 301, Denver, Colorado* 80218 (R18 CA 25478-01)

The aims of this program are: 1) to reduce delay in diagnosis and treatment of endometrial and breast cancer in postmenopausal women, especially those receiving exogenous estrogens, and 2) to increase the quality of diagnosis, treatment and follow-up of patients with these diseases. A demonstration program will be organized in collaboration with the Colorado Regional Cancer Center, the Denver Medical Society, and the Colorado Division of the American Cancer Society, in which physicians and other health care professionals who see postmenopausal women and prescribe estrogens will participate in a cancer surveillance plan. These professionals will be provided with professional information and consultation and with technical assistance in patient education, and will contribute data for evaluation of the program. A supporting and reinforcing community education program directed at women over 45 years of age will also be developed.

CANCER INCIDENCE IN MOTHERS OF DIZYGOTIC TWINS

G. Wyshak, Harvard University, Boston Campus, School of Medicine, Dept. of Preventive & Social Medicine, *25 Shattuck St., Boston, Massachusetts* 02115 (R01 CA 25623-02)

The purpose of this study is to determine whether mothers of twins, who have a higher level of gonadotropins that other mothers, have cancer incidence or cancer mortality rates different from those of controls. The study will be based on a follow-up of the experience of a study group of 3982 mothers who had male-female twins or other polyzygous births in Connecticut during the years 1925-1959; a control group of 3982 women matched pairwise on year of childbirth, age, number of previous children, race and national origin; and a second control group of 3982 women randomly selected from mothers of singletons. In addition, the Connecticut Twin Registry will be searched for male-female twins and other polyzygous births occurring during 1960-1974; we expect to identify mothers of 2500-3000 male-female twins from this search. The Vital Statistics Records will be searched for controls chosen in the ratio of 4:1, and matched on age, race, and index year of birth. These women will be added to the study and the Connecticut Tumor Registry searched for the women in the study and control groups recorded for since 1966 for cancers of all sites. The observed incidence of site-specific cancer will be compared with that expected among Connecticut residents of the same age and sex.

EPIDEMIOLOGY OF CANCER OF THE RENAL PELVIS AND URETER

R.K. Ross, University of Southern California, School of Medicine, Dept. of Community & Family Medicine, *2025 Zonal Ave., Los Angeles, California* 90033 (R01 CA 25669-02)

The proposed research is a continuation of a case-control study of the epidemiology of cancer of the renal pelvis and ureter in Los Angeles County. The study is designed to test for multiple antecedent risk factors or these diseases with special emphasis on prior heavy analgesic consumption, occupational exposures, cigarette smoking, and coffee consumption. The study is in year 2 of a proposed five-year program. The final case group will consist of 200 cases of carcinoma of the renal pelvis and ureter identified by the Los Angeles County/USC Cancer Surveillance Program. Controls are neighborhood controls individually matched to the cases by date of birth (plus or minus 5 years), sex, and race.

Data are obtained by telephone interviews conducted by a trained nurse epidemiologist with question-

naire information focusing on the above items. The study will evaluate the relative importance of each of these suspected risk factors in disease development and, for analgesic usage, the specific analgesic component responsible for increased risk.

EVALUATION OF LOW LEVEL PLUTONIUM & CANCER

C.J. Johnson, Jefferson County Health Dept., *260 S. Kipling St., Lakewood, Colorado* 80226 (R01 CA 25729-01)

Because of documented contamination of about 50 square kilometers of land with plutonium in the vicinity of the Rocky Flats nuclear weapons plant, there is community concern regarding possible health effects for populations living in this area as well as concern for the safety of further residential depelopment near the plant. A preliminary study of age-corrected death rates from leukemia in eight census tracts around the plant and in the city of Golden (a small city near Rocky Flats) compared with a control area consisting of 19 census tracts with a similar population in the relatively uncontaminated part of the county disclosed a significant increase in deaths from leukemia in the contaminated areas.

An evaluation of age-specific death rates (45-64 years) for each of the contaminated areas compared with the control area disclosed a death rate from lung cancer more than twice as great as that for the control area.

I propose to expand the study by evaluating death rates and incidence rates of leukemia, lung cancer, and other types of tumors in these and other study areas in the Denver metropolitan area, by census tracts. Study areas will be selected by known levels of plutonium in surface respirable dust and for inventory levels. This phase of the study will continue through the census year 1980, and will be completed by the end of the calendar year 1981. Cancer death and incidence data will be supplied by the Colorado Health Department, Division of Vital Statistics. The effects of exposure to low levels of plutonium on a general population living in a contaminated area has never yet been evaluated with this epidemiological approach, and the results will be of considerable value in selecting sites for plutonium processing plants and nuclear electric generating plants in relation to population centers.

This study will be followed by a prospective study extending to 1991.

HEPATITIS B VIRUS AND HEPATOCELLULAR CARCINOMA

L.I. Lutwick, University of Iowa, School of Medicine, Dept. of Internal Medicine, *Jessup Hall, Iowa City, Iowa* 52240 (R01 CA 25811-01)

A substantial amount of information linking the hepatitis B virus and hepatocellular carcinoma has been generated along epidemiological and serological lines. The objectives of the research proposed here are to obtain data to more strongly link the virus in the direct production of hepatocellular carcinoma.

Using the techniques of in vitro and in situ nucleic acid hybridization, homologous DNA will be sought to the hepatitis B Dane particle DNA in hepatitis B associated and nonassociated chronic liver disease and malignancy. Attempts will be made to directly localize the homologous DNA to the cell genome by 1) in situ hybridization to metaphase chromosomal spreads from human hepatocellular carcinoma tissue culture line and 2) further evaluation of high molecular weight DNA from chronically infected liver which is hybridizable to viral DNA probe.

In addition, to further understand the events leading from acute infection to chronic infection to malignant transformation, a newly described animal model involving Marmota monax, the common woodchuck, will be investigated for its applicability to the hepatitis B setting. Also, human hepatoma tissue cell lines will be transplanted into nude athymic mice to further observe anti-viral, anti-tumor and immunologic manipulation of the malignant cells.

MICROBIOLOGICAL FACTORS CONTRIBUTING TO COLON CANCER

H.F. Mower, University of Hawaii System, Manoa Campus, John A. Burns School of Medicine, Dept. of Biochemistry & Biophysics, *2444 Dole St., Pacific Biomedical Res. Ctr., Honolulu, Hawaii* 96822 (R26 CA 25859-01)

Chemical causes of colorectal cancer are being sought by the use of bacterial mutagen assay to detect potential carcinogenic substances in human fecal samples. Preliminary epidemiologic work has been done on the incidence of mutagens in feces of Japan Japanese, and Hawaii Japanese, populations of low and high risk for large bowel cancer respectively. We have discovered five classes of fecal mutagens, four are present in higher amounts in the high risk Hawaii-Japanese than in the low risk Japanese population. Two of these four mutagens are closely associated with the fecal transnitrosase. This is an enzyme which we have discovered in certain strains of E. coli, various fecal bacteria and in human colon and stomach tissue. This enzyme can transfer nitroso groups from a wide variety of nitrosamines to a diverse group of amide acceptor molecules such as simple primary and secondary amides, ureas and urethanes. The structure of the product is unknown but different from the structure of the N-nitroso-N-alkyl amides, ureas or ureathanes. All products are direct acting mutagens on the Ames Salmonella tester strain TA98. The enzyme is increased when beef is added to the diet of man or experimental animals.

The identification and structure of these products will be carried out using the techniques of modern chemical investigation such as various procedures of chromatography, NMR, IV, UV, and mass spectrometry.

A newly discovered enzyme, nitrosohydrolase, is also present in fecal bacteria. The enzyme will specifically destroy the product of the transnitrosase, converting these substances into N2, esters, or NO2-and the original acceptor molecule. Mutagen formation is thereby prevented. Both enzymes will be purified, characterized and studied by the modern techniques of biochemistry.

Mechanisms whereby diet and environmental effects alter the fecal mutagens, fecal transnitrosase and fecal nitrosohydrolase will be sought.

MUTAGENS AND LOWER URINARY TRACT CANCER IN HAWAII

A.M. Nomura, University of Hawaii System, Manoa Campus, Pacific Biomedical Research Center, Epidemiology Unit, *2538 The Mall, Honolulu, Hawaii* 96822 (R26 CA 25903-01)

This case-control study will investigate the association of lower urinary tract cancer with chenical mutagens in the urine in two ethnically-distinct groups in Hawaii which have different levels of risk for this disease (high risk for Caucasians and intermediate risk for Japanese). It will also include data on the association of this cancer with smoking cigarettes, drinking coffee, occupational exposures and the use of artificial sweeteners.

Lower urinary tract cancer cases will be identified in the seven major civilian hospitals on Oahu for a period of five years (approximately 104 Caucasian and 92 Japanese cases). We will also recruit surviving prevalent cases who were diagnosed within two years of the start of the study (30 Caucasian and 27 Japanese cases). For each case, two neighborhood controls matched by race, sex and age within five years will be selected and interviewed. Over-night urine samples for battery of mutagen tests (Ames) will be collected from all subjects.

The questionnaires and format for this study will be similar in design to an ongoing case-control study being conducted by the Harvard School of Public Health in three different populations (including the low risk Japanese in Nagoya, Japan). By this arrangement, we will be able to compare the findings between the Japanese in Hawaii and Nagoya in an attempt to identify factors which account for the increase in lower urinary tract cancer among the Japanese in Hawaii. In addition, we will compare data of the Caucasians and Japanese in Hawaii to identify factors which may account for the difference in risk between these two groups which reside on the same island.

FIBROCYSTIC BREAST DISEASE - EPIDEMIOLOGY AND HISTOLOGY

J.L. Kelsey, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (R01 CA 26021-01)

This case-control epidemiological study will examine the relationship between use of oral contraceptives and fibrocystic breast disease categorized histopathologically according to the extent of epithelial atypia; the specific hypothesis stating that there is a positive association between long-term use of oral contraceptives and the degree of epithelial atypia will be tested. Cases will be women who have had fibrocystic breast disease diagnosed from biopsy at four large Connecticut hospitals over a 22-month period. Their slides will be read by a pathologist associated with the study, and classified according to extent of epithelial atypia. Controls will comprise women admitted as inpatients or outpatients to certain surgical services of these same hospitals. Information on oral contraceptive use, demographic characteristics, and other variables of interest will be obtained from cases and controls by means of a structured questionnaire administered by trained interviewers, supplemented by queries to physicians. Previous use of oral contraceptives and exposure to other factors of interest will be studied in four groups categorized according to extent of epithelial atypia, as well as in controls, and the results will be compared. This study should increase our knowledge of the epidemiology of fibrocystic disease and potentially our understanding of the epidemiology of breast cancer, since fibrocystic disease with marked epithelial atypia has been found to be the form of fibrocystic disease most strongly associated with subsequent breast cancer.

EPIDEMIOLOGIC STUDY OF CHILDHOOD GLIOMAS

P.C. Nasca, State Dept. of Health, *Empire State Plaza, Tower Bldg., Albany, New York* 12237 (R01 CA 26194-01)

Our general objective is to determine, by means of an epidemiologic case-control study, the importance of various prenatal and childhood environmental exposures in the etiology of childhood gliomas. Special emphasis will be placed on prenatal and early childhood exposures to drugs, chemicals, radiation, tobacco, immunizations and animals. Selected birth characteristics including maternal age, parity and season of birth will also be examined.

Approximately 400 patients with childhood gliomas should be available for study. This sample size and a control to case ratio of 2:1 shall enable us to investigate the study variables with respect to the more common histologic subtypes. Demographic, pathologic and clinical data will be collected from the hospital records of each patient, utilizing a standardized form. Further data will be collected through telephone interviews with the mothers of each patient and control. These will be validated by comparing the mothers' responses with physician and hospital records.

2.0522,

EPIDEMIOLOGY OF OVARIAN CARCINOMA

E.A. Mortimer, Case Western Reserve University, School of Medicine, Dept. of Community Health, *2109 Adelbert Rd., Cleveland, Ohio* 44106 (R01 CA 26252-01)

The purposes of this study are to confirm and extend or refute certain previously obtained epidemiologic characteristics of ovarian carcinoma, and to see whether direct medical student involvement in epidemiologic research is feasible and productive. The epidemiologic characteristics of ovarian carcinoma to be studied include its higher rates in never-married women, women of low parity and women who have not used oral contraceptives. The study is intended to provide clues as to whether low parity is somehow conducive to, or non-protective for, ovarian carcinoma or whether some unknown ovarian defect predisposes both to sterility or low parity and ovarian cancer. In addition, the previously noted lower rates of a history of mumps, rubella and measles will be

studied by serologic testing of patients with ovarian carcinoma and appropriate controls.

BLADDER CANCER RISK FACTORS IN UTAH

D.W. West, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Family & Community Medicine, *1400 E. 2nd S., Salt Lake City, Utah* 84112 (R26 CA 26362-01A1)

Previous epidemiological studies have identified several risk factors in the etiology of bladder cancer and a national study has been completed recently to determine whether these factors are associated with the disease. This was a case-control study of incidence cases in defined geographic areas and randomly selected population controls. Utah participated in this 12-month study, but the number of cases identified in Utah in 12 months (127) will not allow adequate sample size to perform the multivariate analysis techniques needed to test several important hypotheses. Since coffee and tobacco consumption are low in the Utah population, hypotheses concerning these risk factors can be studied without the problems found in other populations where the groups of non-users are small. In particular, coffee can easily be studied in Utah, as well as caffeine and the interaction of both with tobacco in the etiology of bladder cancer. Urban-rural differences and an increasing incidence for older males have also been noted in the state and identification of risk factors for these findings may suggest new hypotheses. The proposed plan will utilize the same design as used in the national study, but collect more data on coffee consumption. This will be done for two years and a year will be necessary for data analysis.

2.0524,
EPIDEMIOLOGIC AND HLA STUDY OF LEUKEMIA

M. Szklo, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 CA 26500-01)

The major objective of this research is to study the epidemiology of chronic lymphocytic leukemia (CLL), focusing upon possible associations with sources of chronic antigenic stimulation, occupations and familial factors. A second objective is to define possible HLA associations with CLL.

To accomplish these objectives, the study will be divided into three components. In Part I all new cases of CLL first diagnosed in Baltimore SMSA from June 1969 through May 1979 will be identified. Medical chart review of all these cases and two groups of matched controls will be performed.

Part II will consist of an interview study of all cases and controls, identified in Part I, who are still alive. For cases and controls who have died or are lost to follow-up, a mailed questionnaire will be sent to next-of-kin, spouse or closest friend.

Part III has three components, all involving HLA testing. These components include an HLA case-control study, a prospective HLA study of 'rapidly progressive' versus 'indolent' cases of CLL, and HLA testing of families with two or more cases of CLL, lymphoproliferative diseases and/or autoimmune diseases.

2.0525,
PROSPECTIVE STUDY OF DIET AND CANCER IN WOMEN

F.E. Speizer, Harvard University, Boston Campus, Peter Bent Brigham Hospital, *721 Huntington Ave., Boston, Massachusetts* 02115 (R01 CA 26560-01)

This study is designed to address questions regarding the possible association between the intake of various dietary components and cancer of the breast and large bowel, as well as other disease outcomes. This is to be done by taking advantage of an existing prospective study of risk factors for breast cancer in 121,000 women who complete a mail questionnaire on a biennial basis. This investigation will require the development of a short dietary questionnaire, administration of this questionnaire to the entire cohort, and subsequent follow-up on a biennial basis to gather data on the development of specific cancers of interest.

The questionnaire will be designed to provide relative scores for individuals on: intake of animal fat, vegetable fat, cholesterol, protein, fiber, Vitamin A, and 'trans' fatty acids. Data on potential confounding factors, including physical activity, for risk of breast cancer and large bowel cancer is being collected and will be controlled by multiple logistic analyses. To validate the questionnaire, 200 subjects will complete detailed 7-day food use diaries four times over 1 year period. Blood specimen from 400 women at the extremes of consumption histories will be assessed for lipids, carotene, and vitamin A levels. These specimens will be preserved for possible subsequent endocrinologic determinations.

Outcome measures will include both fatal and non-fatal cancer incidence rates. Reported cases of cancer will be documented by obtaining copies of hospital records and causes of death will be obtained from death certificates as well as hospital records.

Over the course of 4 years of follow-up, sufficient cases of breast and large bowel cancers are expected to occur in the cohort to permit better than 90% chance of detecting a 1.5-fold risk for breast cancer and a 2-fold risk of large bowel cancer.
SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $125,592

2.0526,
PROSTATIC CARCINOMA IN AMERICAN BLACKS

J. Kovi, Howard University, School of Medicine, Dept. of Pathology, *2400 6th St. N.W., Washington, District of Columbia* 20001 (R26 CA 26679-01)

The objective of the proposal is to identify some of the factors which may be etiologically related to carcinoma of the prostate in the high-risk American black population. About 200 cancer patients and 200 age-matched controls will be included in this study. Specifically, the study will 1) investigate by pretested questionnaires whether dietary and/or lifestyle habits of American blacks are related to the high incidence of prostatic carcinoma, 2) examine the association of carcinoma and morphologic manifestations of aging within the gland in necropsies, 3) explore by atomic absorption spectroscopy the relationship between certain trace metals and carcinoma, in prostate glands removed at autopsy, 4) analyze the vascular patterns in three dimensional reconstructions, in both incidental and invasive carcinoma from necropsy cases, 5) measure by radioimmunoassay free and bound testosterone, dihydrotestosterone, prolactin, estradiol and estrone levels in patients and controls, 6) correlate plasma hormone levels with presence or absence of androgen and estrogen receptors in prostatic tissue and with the clinical response, 7) evaluate the overall capacity of measurement of the counter immunoelectrophoresis (CIEP) method for detection of serum specific acid phosphatase in patients and controls. The clinical features of patients with cancer will be evaluated by established clinical methods and the disease will be staged. Whole prostate glands from necropsy cases will be analyzed for morphologic changes according to a specific protocol. Hormone receptors will be determined by sucrose density-gradients, ultracentrifugation and protamine precipitation. Significance of all the above data will be determined by appropriate statistical analyses.

2.0527,
PATTERNS OF CARE IN ONCOLOGY

E.R. Greenberg, Dartmouth College, School of Medicine, Dept. of Community Medicine/Medicine, *P.O. Box 833, Hanover, New Hampshire* 03755 (R18 CA 26630-01)

Members of the Norris Cotton Cancer Center, the Dartmouth Medical School, and the Vermont Regional Cancer Center propose to conduct an epidemiologic study of the patterns of lung cancer patient care in New Hampshire and Vermont. The study is designed to determine the nature of geographic variations in care among patients in our rural area and to test whether such differences are related to differences in the local availability of specialized cancer treatment facilities and whether they can account for geographic differences in survival. Using our two-state, population-based tumor registry to identify cases, we will conduct reviews of medical records to determine patient characteristics, functional status, tumor stage, and detailed treatment information. An independent slide review will provide information on tumor histology. We will analyze these data using univariate and multivariate methods to identify the interrelationship of the patterns of treatment with services available and patient survival. The study will allow us to test one of the basic assumptions underlying cancer control programs, i.e., that identifiable populations in the United States lack easy access to sophisticated cancer treatment facilities, and therefore, receive suboptimal care with resultant poor outcome.
SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $139,230

2.0528,
POPULATION BASED STUDY OF LOWER URINARY TRACT TUMORS

J.W. Meigs, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (R26 CA 26692-01)

The general purpose of this proposal is to further knowledge of the etiology and epidemiology of bladder and other lower urinary tract tumors. Some of the particular questions we wish to answer are: 1) How important are the well documented risk factors in Connecticut? 2) How great are these risks and is the etiology of non-bladder lower urinary tract tumor the same as that of bladder tumor?

As part of a national study, data on a large number of suspected risk factors for bladder cancer have been collected by home interview on all new cases of lower urinary tract tumor diagnosed in Connecticut residents during 1978 (590 cases are expected: 540 bladder and 50 other). The statewide reporting system which supports the Connecticut Tumor Registry has been used for case identification and the Connecticut Tumor Registry will provide tumor data. Identical data have been gathered on a random sample of 1,980 Connecticut residents of the same age and sex. Risk factors included are smoking, occupation industrial exposures, artificial sweetener and coffee consumption, hair dye use, quality of drinking water, passive smoking, and skin exposure to a variety of industrial and household materials. Data on the latter two factors and inclusion of non-bladder lower urinary tract tumors are unique to Connecticut. Funds are herein being requested to analyze the Connecticut portion of this large body of data; to extend data collection to include another 15 months' cases of non-bladder lower urinary tract tumors; to reinterview a sample of controls and bladder cancer cases and all non-bladder lower urinary tract cases to obtain data on analgesic abuse; and to describe the pattern of incidence and mortality of bladder and other lower urinary tract tumors using data in the Connecticut Tumor Registry.

NUTRITION AND CANCER

T.C. Campbell, Cornell University, Ithaca Campus, New York State College of Agriculture & Life Science, Dept. of Nutritional Sciences, *Ithaca, New York* 14850 (P01 CA 26755-01)

The relationship of nutrition and cancer will be explored in separate studies which focus on biochemical mechanisms, on influences of specific dietary components, including protein, carbohydrates, vitamins, and dietary fiber, and on development of epidemiological information.
SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $372,554

2.0530,
PROGRAM IN BIOMETRICS OF CANCER EPIDEMIOLOGY

I.D. Bross, Roswell Park Memorial Inst., *666 Elm St., Buffalo, New York* 14263 (R01 CA 27514-01)

We request renewal of support for this program in biometric research in cancer epidemiology. The aim of the program is to develop new technology or to extend previously developed technologies for scientific data-utilization. This includes computerized biostatistical and mathematical models capable of handling the complexities of epidemiological study situations. It also includes the application of the natural language technology developed in modern linguistics

to improve each of the 9 steps in the process of data-utilization. This new technology is designed to work on real (as opposed to hypothetical or ideal) data and to produce practical results in primary prevention that would provide immediate aid in cutting cancer death rates in future years. The technology would be initially applied to the following primary research targets: (1) Further studies of the health effects of low-level ionizing radiation, (2) follow-up studies of the iatrogenic diseases that may have been produced by the surgical adjuvant treatments for breast cancer, (3) applications of natural language computing systems to recoding of Tri-State Survey data, development of computerized archives, and planning of a largely automated procedure for rigorously assessing the validity of a scientific argument. After a two-year rebuilding period, further lines of research will be considered.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $62,491

2.0531,

EPIDEMIOLOGY & CANCER REGISTRIES IN THE PACIFIC BASIN

B.E. Henderson, University of Southern California, School of Medicine, Dept. of Community & Family Medicine, *2025 Zonal Ave., Los Angeles, California* 90033 (R13 CA 27751-01)

This proposal requests funds for travel and per diem for fifty (50) participants to the Third Symposium on Epidemiology and Cancer Registries in the Pacific Basin. The first and second symposia (1975 and 1978) provided a forum for the exchange of information on 1) the design and conduct of cancer registries, and 2) the status of research in cancer epidemiology in nineteen participating countries and territories of the Pacific. In addition, important collaborative research on several cancers (e.g., lung, breast, nasopharynx and liver) was developed.

The Third Symposium will be designed to provide new demographic information from existing cancer registries (e.g., secular trends, occupational risk) and to introduce data from developing registries in the People's Republic of China, Korea, and the South Pacific. In addition, ongoing collaborative research will be reviewed and new projects designed during workshops on cancer sites of particular interest - liver, breast, stomach, colo-rectal, lung, urinary bladder, and prostate and testis. Dr. Henderson will visit several of the participating programs prior to the Third Symposium to provide added stimulus to the meeting preparations.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $77,374

CHILDREN'S CANCER STUDY GROUP A

J.Z. Finklestein, University of California, Los Angeles Campus, Los Angeles County Harbor General Hospital, *1000 W. Carson St., Torrance, California* 90509 (R10 CA 14560-07)

This proposal is to continue to develop and increase the participation of Harbor-UCLA Medical Center and affiliated institutions in all phases of the Children's Cancer Study Group. Clinical research protocols are developed in the Children's Cancer Study Group to investigate pertinent questions regarding the natural history, treatment and epidemiology of childhood cancer. These studies will be carried out by means of a coordinated program involving chemotherapists, surgeons, radiotherapists, and pathologists. One major goal of the Children's Cancer Study Group is to design and coordinate clinical investigations for various neoplastic disorders of children. These investigations include controlled clinical trials in leukemia and solid tumors of childhood, evaluations of newly developed therapeutic agents, and studies of the effects of immunotherapy and immunosuppression.

COMPREHENSIVE CANCER CENTER--CORE SUPPORT GRANT

G.D. Hammond, University of Southern California, School of Medicine, Dept. of Pediatrics, *2025 Zonal Ave., Los Angeles, California* 90033 (P30 CA 14089-06)

This is a Cancer Center Core support grant providing Core support for administration, program, and research efforts for the Los Angeles County/University of Southern California Comprehensive Cancer Center. This Center is one of the nineteen designated comprehensive cancer centers in the United States.

Cancer activities at this Center constitute one of the largest University-based cancer research and control efforts in the nation. Principal effort is focused in a Basic Research Program including activity in Chemical Carcinogenesis, Tumor and Cell biology, Lymphocyte Biology, and Immunology; in Clinical Cancer Investigations including Tumor Imaging, Radiopharmacy, Hematopathology, Clinical Immunology, Clinical Pathology; Surgery, Chemotherapy, Immunotherapy, Phase II and III Trials, and Clinical Pharmacology; in Biostatistical and Epidemiological studies of major import; and in an extensive Cancer Control Program reaching throughout the southwestern United States. In addition, the Center conducts an extensive training and education program in the above specialty areas.

Nearly 150 faculty members and scientific investigators of the University and affiliated institutions are involved in this effort, with extramural funding for research, education, and control. The Center also acts as the Operations headquarters for the National Children's Cancer Study Group.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $1,652,069

2.0535,

GENETIC EPIDEMIOLOGY AND NATURAL HISTORY OF CANCER

N.L. Petrakis, University of California, San Francisco Campus, School of Medicine, Dept. of Epidemiology & International Health, *551 Parnassus Ave., San Francisco, California* 94122 (P01 CA 13556-08)

The proposed epidemiological and experimental studies of breast cancer will investigate host, agent and environmental factors in order to trace the etiology and pathogenesis of this disease. We will investigate host factors from the perspectives of genetics, cytopathology, physiology and biochemistry. We will analyze carcinogenic agents which may be secreted into the breast fluids of women and the role of these agents in the initiation and promotion of breast cancer. We will explore certain nutritional components of the environment and their possible role in breast cancer etiology. We will also investigate health practices of women with regard to early breast cancer detection.

These studies will hopefully allow us to suggest new hypotheses for the etiology of breast cancer and to predict more accurately the risk of breast cancer for asymptomatic women. Elucidation of processes of initiation and pathogenesis of breast cancer could lead to the development of preventive programs against this disease.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $696,179

2.0536,

RESEARCH IN ENVIRONMENTAL CANCER

N. Nelson, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016 (P30 CA 13343-07)

This proposal seeks continued support for a NCI Center Grant entitled 'Research in Environmental Cancer'. This Center Grant provides core support for the Institute in the area of cancer research, including partial salary support for professional staff, developmental funds, and limited support for items of shared equipment and central services. The research and teaching program in cancer at the Institute has the broad objective of identifying environmental causes of cancer and developing methods for the control of carcinogenic hazards. The program is interdisciplinary in character and ranges from studies at the subcellular level on mechanisms of action to whole animal, epidemiological and environmental studies.

This NCI Center Grant for 'Research in Environmental Cancer' is complementary to the larger National Institutes of Environmental Health Sciences Center Grant for 'Research in Environmental Health Sciences', and serves to strengthen the Institute's program in cancer. The activities of the Institute in the area of environmental cancer are included as one of the divisions of the NYU Cancer Center although funding for this purpose is provided solely through the present grant.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $320,990

ENVIRONMENTAL CARCINOGENESIS

E.L. Wynder, American Health Foundation Inc., *320 E. 43rd St., New York, New York* 10017 (P01 CA 12376-08)

This program project grant has supported an integrated multidisciplinary program in environmental carcinogenesis relating retrospective case-control epidemiological studies and experimental research. The latter includes cell culture, animal model, and human subject investigations. Proposed studies by organizational division in the forthcoming period are: 1) Epidemiology: various cancer studies in the U.S. and overseas, emphasizing GI tract and breast cancer. 2) Nutrition: endocrine-related cancer studies via hormonal effects of high-fat diets in various human populations; also dietary studies on colon carcinogenesis utilizing fecal analyses. 3) Molecular Biology and Pharmacology: study of the mechanism of the high-fat effect on breast cancer development using animal models and cell cultures; also the mechanism by which alcohol may act as a cocarcinogen in oral cavity cancer. 4) Experimental Pathology: model systems for the study of the pathogenesis of tumor development. 5) Experimental Carcinogenesis: investigation of the carcinogenic action of hydrazines, nitrosamines, and methylated polynuclear hydrocarbons, in addition to bracken fern. 6) Occupational Health and Toxicology: assessment of cancer risk to welders as a model population.

2.0538,

SOUTHWEST ONCOLOGY GROUP (STATISTICS)

E.A. Gehan, University of Texas, University of Texas System Cancer Center, M.D. Anderson Hospital & Tumor Inst., Dept. of Biomathematics, *c/o Texas Medical Ctr., Houston, Texas* 77030 (R10 CA 12014-11)

The functions of the Statistical Office of the Southwest Oncology Group are: (1) To provide analyses of ongoing clinical studies in cooperation with the chairman of each study. Achievement of objective (1) provides for the central registration of all patients and studies, and provides for the surveillance, monitoring, storage, and processing of all data collected during group studies. (2) To provide for the review of all proposed protocols and to suggest an experimental design for each study. (3) To work in close cooperation with the Chairman of the Southwest Oncology Group in the administration of group studies. (4) To perform research on the statistical aspects of group studies to improve the efficiency of ongoing and future clinical trials. (5) To carry out long-term analyses of group studies to determine, for example, whether survival has been improving with time, and which clinical and laboratory variables seem important in relation to the response and survival of a cancer patient.

NATIONAL WILMS' TUMOR STUDY

G.J. D'Angio, American Academy of Pediatrics, *1801 Hinman Ave., Evanston, Illinois* 60204 (R10 CA 11722-11S1)

Modern treatment methods have led to a major improvement in the survival rate of children with Wilms' tumor. Combined therapy using surgery, radiation therapy, and chemotherapy now cures more than 85% of patients. However, the outlook is poor for those with unfavorable histology, where the 2-year survival is less than 30%; and for those with any histology and metastases at diagnosis (about 50% survival). More effective means of treating these patients must be developed. At the same time, all treatments have their risks and complications, and refinements of therapy for those with a good prognosis are needed so as to achieve maximum survival with the least morbidity. NWTS-1 is now complete, and its primary and secondary objectives have been achieved. 'Natural history' and epidemiologic information has been reported. Gross and microscopic features associated with an unfavorable outlook have been identified. Combined therapy using actinomycin-D (AMD) and vincristine (VCR) is superior to the use of either agent alone. Routine radiation therapy (RT) is not needed in all children with early stage disease. Review of RT given to children with more advanced stages, however, left to be defined the role of radiotherapy in the modern management of these patients. NWTS-2 is now in the stage of data analysis. Preliminary results suggest that 6 months of AMD and VCR maintenance therapy is satisfactory for Group I children, none of whom receive RT, and that the addition of adriamycin to AMD and VCR gives better results than the use of AMD and VCR alone. NWTS-3 will build on the first two studies and use the staging system developed therefrom. The questions presently planned are: (1) Is two months of AMD and VCR maintenance therapy enough for Stage I? (2) Is RT needed for Stage II? (3) Does 1000 rad suffice for the treatment of Stage III? (4) Can a better drug regimen be devised for Stage IV and unfavorable histology? (5) What are the late adversities of successful treatment in NWTS patients?

RESEARCH AND CLINICAL RADIATION THERAPY CENTER

S. Kramer, Thomas Jefferson University, Jefferson Medical College, Dept. of Radiation Therapy & Nuclear Medicine, *1025 Walnut St., Philadelphia, Pennsylvania* 19107 (P01 CA 11602-10)

Support is requested for an expanded multi-disciplinary integrated program of cancer research including studies of: (a) Cell and tissue response to hyperthermia, combinations of drugs and radiation, as well as environmental and other agents. (b) Physics and dosimetry of high energy photons, electrons and neutrons as well as treatment optimization with computer assisted tomography, ultrasound and computer treatment planning. (c) Clinical trials of aggressive radiation therapy based on observations and information from these and other scientific studies and clinical observations. (d) Assessment of the quality of life and function and late effects of long-term survivors after definitive radiation therapy. (e) Development of cancer patient information system for quality control of care and for research into clinical success and failure.

Emphasis will be placed on inter-disciplinary and inter-departmental exchange of information and understanding as well as clinical care and teaching.

2.0541,

CELL CONTROL IN INTEGUMENTAL CANCER

E.J. Van Scott, Temple University, School of Medicine, Dept. of Dermatology, *3322 Broad St., Philadelphia, Pennsylvania* 19122 (P01 CA 11536-11)

CANCER BIOLOGY: In vitro cell kinetics and growth potential of normal keratinocytes and fibroblasts and these cell types from benign and malignant hyperplastic skin disease of hyperplasia are compared. Cellular defects in these cell types, i.e., defect in DNA synthesis, response to hormones, DNA repair, mucopolysaccharide and collagen metabolism are studied. Blood levels of polypeptide hormone, epidermal growth factor, and its role in hyperplastic cutaneous disorders are determined.

CARCINOGENESIS: Carcinogenic potential of pharmacologic agents (e.g., mechlorethamine, psoralen-ultraviolet light) is monitored in laboratory animals which have received cutaneous administration of such agents and in patients receiving such agents therapeutically.

CANCER THERAPY: Therapeutic control of the lymphoma mycosis fungoides by single agents and combinations thereof is pursued. Agents include topical and systemic drug materials as well as physical agents.

BIBLIOGRAPHIC REFERENCES: Haynes, H. A. and Van Scott, E. J.: Chapter on cutaneous lymphomas in: Dermatology in General Medicine, ed. T. B. Fitzpatrick, et al., McGraw-Hill, New York, pp. 749-767, 1979. Tam, D. W., Van Scott, E. SOCIAL EPIDEMIOLOGY AND CONTROL OF CANCER

S. Graham, State University of New York, Health Science Center at Buffalo, School of Medicine, Depts. of Sociology/Social & Preventive Medicine, *3435 Main St., Buffalo, New York* 14214 (P01 CA 11535-10)

OVERALL OBJECTIVE, BACKGROUND, AND RATIONALE: The prime objective of this program is to investigate the epidemiology of cancer at various sites, particularly those in which there is evidence of a significant social component. Cancer at a large number of sites has been shown to have a social component in its epidemiology. This is true of cancer of the upper GI tract, the lung, breast, testis and cervix, to name a few. Our concern is to examine further the social factors involved in these diseases and to further elucidate the meaning of relationships already discovered. Factors of particular interest include diet, alcohol ingestion, marital activities, and smoking, as they interact with both physiologic and behavioral variables to increase or decrease risk of cancer. Building on epidemiologic findings, our concern also will be to conduct inquiries into ways of obtaining behavior change, such as breast self-examination and stopping smoking, which will protect the public against cancer.

CORE CANCER CENTER SUPPORT GRANT

R.A. Cooper, University of Rochester, School of Medicine & Dentistry, Dept. of Pathology, *601 Elmwood Ave., Rochester, New York* 14627 (P30 CA 11198-11)

The University of Rochester Cancer Center has developed and continues to use a Matrix Management Model to accomplish its specific goals, which include: (1) Development of a Community Based Treatment and Clinical Research Program in Monroe County, (2) Development of an Outreach Program in the adjoining eight counties of the Genesee-Finger Lakes Health Systems Area, (3) Development of a Comprehensive Cancer Education Program, (4) Development of a focused Basic Research Program emphasizing Biochemical Genetics, Biochemical Radiopharmacology, and (5) Effective participation in the National Cancer Institute above and beyond the Cancer Centers Program. The integrating research theme of the Center is the comparative study of damage and repair of macromolecules and organelles (DNA, RNA, and membranes) critical to cell survival and to an understanding of cancer cause and prevention and the design of new treatments.

CHILDREN'S CANCER STUDY GROUP A

R.L. Chard, Childrens Orthopedic Hospital & Medical Center, *4800 Sand Point Way N.E., Seattle, Washington* 98105 (R10 CA 10382-14)

This proposal is for continuation of four year renewal of research in the natural history, epidemiology, statistical conduct, design, collation and treatment of childhood malignant diseases in a sophisticated multimodal manner. This institution has been a member of the Children's Cancer Study Group since 1959. Over the past 20 years very strong referral pattern for children with malignant disease has been established throughout the Pacific Northwest and continues to grow. From October 1, 1978 through July 31, 1979, 92 children with childhood malignancies were examined and treated on Children's Cancer Group protocols. Thirty-one of these cases were leukemia and 61 were solid tumors. In addition, 12 more patients with acute leukemia were treated on a pilot protocol with the National Cancer Institute, Pediatric Division, in conjunction with Dr. A. Bleyer of this institution and Dr. Poplack of the NCI Pediatric Division. This study will be directed primarily at the use of high-dose intravenous methotrexate in an effort to treat CNS leukemia successfully. In addition to the Children's Cancer Study Group programs we are continuing collaboration with Dr. E. Donnall Thomas in bone marrow transplantation. Eighteen bone marrow transplants have been done in this hospital since October 1, 1978. Also continuing is Dr. I. Bernstein's work in tumor immunology, particularly with emphasis on monoclonal antibody studies done in mice and we hope to soon transfer this to human leukemia cells. Dr. W.A. Bleyer continues to work with the National Cancer Institute in his high-dose methotrexate pharmacologic studies and studies of intraventricular methotrexate and aminopterin. This program continues under the pediatric oncology unit at the Fred Hutchinson Cancer Research Center.

CHILDREN'S CANCER STUDY GROUP A

M.E. Lahey, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Pediatrics, *1400 E. 2nd S., Salt Lake City, Utah* 84112 (R10 CA 10198-13)

The above-named professional personnel propose to collaborate with other members of CCSG as well as with other members of other cooperative study groups, in research on leukemia, malignant solid tumors and closely related disorders in children. The chief purpose of the CCSG is to cooperate in several aspects of research in malignant disease in children (i.e., the natural history, epidemiology) and in particular to develop, evaluate and improve methods of diagnosis, prognosis and treatment of malignant disease in children.

Special emphasis will be placed on the study of new combinations and new schedules of already established chemotherapeutic agents as well as on the evaluation of new anti-cancer agents and new modalities of therapy.

The Principal Investigator is Chairman of the Histiocytosis Committee and has recently received approval by CIB of a new protocol designed to study this disorder in depth with particular attention to clinical and histologic features of prognostic significance, improved therapy and comprehensive immunologic evaluation. The prognostic significance of certain clinical features developed by CCSG has been tested and acclaimed by other chemotherapy groups.

CANCER EPIDEMIOLOGY - STATISTICAL METHODS

N. Mantel, George Washington University, Columbian College Arts & Sciences, Dept. of Statistics, *2121 Eye St. N.W., Washington, District of Columbia* 20037 (R01 CA 15686-05S1)

The spontaneous occurrence of cancer in humans, or induced occurrence in laboratory animals, reflects the interplay of many variables. Also multivariate in nature are the factors influencing survival times or remission times of individuals with cancer, whether treated or left untreated. The multivariate statistical problems which arise may relate to identifying individually important variables which may be causative, making prognoses of survival or other predictions for cancer patients with a specified multivariate vector and seeking to identify optimal therapeutic procedures for such patients. Data available for such analyses may be prospective or retrospective in nature, and for the prospective case will generally involve incomplete observation. Recent developments in mathematical models and statistical approaches for relating response to multivariate regressors, specifically models involving hazard functions and generalized logistic regression, open the way to handling such problems, and it is the effective use of such models and approaches that I plan to study. In instances these approaches may bear modification as, say, using a classification approach when data are abundant but variables to be studied few in number. I anticipate that tie-ins with other problems of cancer epidemiology will develop. Related, or variant methods, may be appropriate in the study of potential environmental carcinogens. Methods for safety evaluation of such agents represent a preventive epidemiology approach.

CANCER CENTER SUPPORT GRANT

L.H. Piette, University of Hawaii System, Manoa Campus, Pacific Biomedical Research Center, *2538 The Mall, Honolulu, Hawaii* 96822 (P30 CA 15655-05)

This continuation proposal is in support of the CORE activities of the Cancer Center of Hawaii. Identified under CORE support are programs in Basic Cancer Research, Clinical Research, Cancer Epidemiology, Data Resources, and Cancer Control. The grant supports facilities in biochemistry, carcinogenesis, tumor cell culturing, electron microscopy and animal facilities. Research in the Cancer Center of Hawaii is focused on Cancer Epidemiology, Environmental Carcinogenesis, Cellular Immunology, Immunotherapy, Hyperthermia and Experimental Chemotherapy.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $394,183

LEUKEMIA - LYMPHOMA PROGRAM

S.P. Balcerzak, Ohio State University, Columbus Campus, School of Medicine, Dept. of Medicine, *370 W. 9th Ave., Columbus, Ohio* 43212 (P01 CA 15147-06)

The overall objective of this program is to provide more effective therapy for patients with leukemia and lymphoma. Research will be conducted in two areas - immunology and chemotherapy. Immunologic studies will characterize further the immune defects in patients with untreated lymphoma, determine the effects of therapy on the immune system of these patients and employ an animal model of lymphoma to evaluate immunotherapy as an adjunct to chemotherapy. Chemotherapy studies will focus on adriamycin. Radiolabeled drugs will be used to study the pharmacokinetics of adriamycin and its metabolites. Adriamycin cardiotoxicity will be described in terms of structure, biochemistry and function in animal models and in man. Agents to ameliorate or treat adriamycin cardiomyopathy will be investigated.

CANCER CENTER SUPPORT GRANT

N.I. Berlin, Northwestern University, Chicago Campus, School of Medicine, Dept. of Obstetrics & Gynecology, *303 E. Chicago Ave., Chicago, Illinois* 60611 (P30 CA 15145-05)

The objective of the Cancer Center at Northwestern University is to maintain an organizational structure and an environment within the University which will bring together basic scientists, clinical investigators, clinicians and educators leading to: (1) collaborative basic and clinical research in cancer, (2) the most effective use of existing knowledge through collaborative programs for the care of the patient, (3) enhancement of the extent and quality of cancer care in the community, and (4) development of a physical facility.

ANOVULATION & EPIDEMIOLOGY OF HORMONE-RESPONSIVE TUMORS

R.B. Wallace, University of Iowa, School of Medicine, Dept. of Preventive Medicine & Environmental Health, *Jessup Hall, Iowa City, Iowa* 52240 (R01 CA 15104-07)

This proposal is for continuation of our work investigating the etiology and pathogenesis of important hormonally-responsive tumors using epidemiologic studies supported by relevant clinical endocrinologic investigations.

For years 07-09 of grant CA-15104, we propose to continue surveillance of a cohort of women, who have prospectively recorded detailed menstrual cycle patterns and reproductive events, for incident breast cancers. This is to determine if special antecedent patterns and events can be elucidated which are predictive of breast cancer and also yield clues to hormonal defects. In this cohort, we also plan to identify women with hysterectomy, obtain clinical and pathologic records, and correlate cycle patterns with benign uterine myomas.

We also propose a case-control to further explore the etiology and pathogenesis of uterine myomas, an important cause of surgery and female morbidity in the U.S.A. Variables to be studied include menstrual and reproductive events implicated in breast, endometrial and cervical cancer, the use of medications including gonadal hormones and other drugs affecting prolactin secretion or the pituitary-ovarian axis, demographic and occupational features, and related systemic morbid events.

It is further proposed to explore our 'anovulatory hypothesis' among selected patients with myomatous disease in the case-control study. Differential levels of estrogen and progesterone receptors will be sought in tumor tissue and control myometrial tissue. Further, to explore the possibility of luteal phase inadequacy among these patients, manifested by subnormal serum progesterone compared to estrogen levels, basal body temperatures and serum steroid hormone and gonadotropin levels be done through a menstrual cycle in a group of women with myomatous disease and an appropriate control group.

GENE EXPRESSION, VIRUS REPLICATION AND CELL GROWTH

P.I. Marcus, University of Connecticut, Storrs Campus, School of Liberal Arts & Sciences, Dept. of Microbiology, *Storrs, Connecticut* 06268 (P01 CA 14733-07)

Specific areas of research in this program project include: adaptive response of cells to the carcinogen/mutagen MNNG; role of MNNG-adaptation to DNA repair processes and protection against carcinogens/mutagens; molecular aspects of gene regulation by the cyclic AMP-dependent protein kinase system of lymphomas cells; cAMP-mediated alteration of cellular proteins; translation discrimination by cytoplasmic regulatory proteins; the relationship of stored mRNP to polysomal mRNA; characterization and function of translational control (tc)RNA; assembly mechanism for membrane-viruses; alterations in cellular gene expression by abnormal proteins; nonglycosylated membrane-associated viral protein; phosphorylation of ribosome-associated components in virus-infected cells; mechanism of inhibition of cellular macromolecular synthesis by viruses; phosphorylation of protein synthesis initiation factor; host factors in viral interference; the interferon system, mechanism of action and induction; dsRNA as the interferon inducer moiety of viruses; the mechanism(s) of cell killing by viruses, cell persistence in persistent infection; homotypic defective-particle interference; intrinsic interference.

Viruses and virus mutants used include: vesicular stomatitis, Sindbis, reovirus, mengo, herpes, pseudorabies, rabies defective particles, rubella, Newcastle disease, and vaccinia. Cell lines used include: mouse S49 lymphoma, mouse C3H/10T1/2, GMK-Vero and BSC, BHK, human trisomic 21, HeLa, HEp2 and mouse L(Y).

EPIDEMIOLOGY OF CANCER IN A LOW RISK GROUP

R.L. Phillips, Loma Linda University, School of Health, Dept. of Biostatistics & Epidemiology, *Loma Linda, California* 92354 (R01 CA 14703-05S1)

It is difficult to study the relation of diet to cancer in the USA because of uniformity of dietary practices. Seventh-Day Adventists (SDAs) are a conservative religious group who do not smoke or drink by church proscription, and about 50% of them do not use meat or coffee. SDAs are very health oriented, and many of them abundantly use whole grains and other unrefined foods. For most cancer sites unrelated to smoking, previous studies have demonstrated that mortality rates in SDAs are about 70% of general population rates. This ongoing prospective study seeks to confirm these mortality differences with incidence data and to determine the specific component(s) of the SDA lifestyle which account for the low risk of non-smoking-related cancers in SDAs. Detailed demographic and lifestyle characteristics of 67,000 California SDAs over age 25 will be collected. For a 5-year perod, all deaths and new cancer cases will be ascertained via annual contacts and review of hospital records for reported hospitalizations. Detailed characteristics and cancer incidence and survival rates of SDAs will be compared to a general population sample. Furthermore, we will be able to compare risk of major cancer sites between subgroups of SDAs with different degrees of adherence, or duration of exposure, to various habits unique to SDAs (i.e. lifetime vegetarians vs heavy meat consumers, etc.).

EXOGENOUS MATERNAL HORMONES AND CANCER IN DAUGHTERS

A.L. Herbst, University of Chicago, School of Medicine, Dept. of Obstetrics & Gynecology, *5801 S. Ellis Ave., Chicago, Illinois* 60637 (R01 CA 20084-04)

The Registry for Research on Hormonal Transplacental Carcinogenesis continues its investigation of the epidemiology, pathogenesis, biologic characteristics, management and prognosis of human genital cancers that develop after intrauterine exposure to exogenous sex hormones. A computerized data bank that contains carefully monitored and doubly checked details for each case forms the basis for this research. We shall continue active canvassing of treatment centers and tumor registries in order to obtain all cases of clear cell adenocarcinoma of the genital tract occurring in females born after 1940, with or without a history of hormone exposure, as well as all cases of other types of genital cancer that develop in individuals exposed to either diethylstilbestrol (DES) or any other type of sex hormones, including those of steroidal nature. Detailed clinicopathologic correlative studies will be directed toward a wide variety of host and cancer characteristics that may be related to the behavior of the tumor (i.e., histology, depth of invasion, mitoses, grade and location). Of particular interest are squamous cell carcinomas of the vagina and cervix that arise in the exposed. The investigation of lesions that precede clear cell adenocarcinoma will continue. Knowledge of treatment and prognosis of these lesions will be expanded. We shall remain a source of scientific information and consultation for this problem.

BIBLIOGRAPHIC REFERENCES: Herbst, A.L., Norusis, M.J., Rosenow, P.J., Welch, W.R., and Scully, R.E.: An analysis of 346 cases of clear cell adenocarcinoma of the vagina and cervix with emphasis on recurrence and survival. INTERNATIONAL CASE-CONTROL STUDY OF BLADDER CANCER

A.S. Morrison, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115 (R26 CA 18660-04)

The objectives of this study are: 1. Estimation of relative incidence of lower urinary tract cancer associated with coffee drinking in three areas - Boston, Massachusetts; Manchester, England; and Nagoya, Japan - which vary with respect to exposure rates and ethnic compositon. 2. Estimation of relative incidence associated with drinking other beverages, with smoking, with certain occupational exposures, and use of analgesics and artificial sweeteners. 3. Estimation of relative incidence for each exposure according to histologic type. 4. Estimation of incidence rates and attributable risk measures in each study area.

By home interview, exposure histories will be obtained for about 500 newly diagnosed cases, and an equivalent number of controls, drawn from a geographically defined population, in each study area. Interviewing has been completed in Boston, and will be completed in mid-1979 in both Manchester and Nagoya. Analysis of the Boston data is in progress.

CANCER CENTER COMMUNITY OUTREACH DEVELOPMENTAL GRANT

J.E. White, Howard University, School of Medicine, Dept. of Oncology, *2400 6th St. N.W., Washington, District of Columbia* 20001 (R18 CA 18510-03S1)

The purpose of this Outreach Developmental Program is to facilitate the coordination of cancer control activities in the Matropolitan Washington, D.C., area. The vehicle for effecting this is the Cancer Coordinating Council for Metropolitan Washington (CCCMW). The Council is comprised of representatives from the followng five institutions: The Howard University Cancer Center, the Georgetown University Vincent T. Lombardi Cancer Research Center, the George Washington University, the District of Columbia's Department of Human Resources, and a single membership for the three American Cancer Society Divisions in this Metropolitan area.

Assisted by a Cancer Advisory Board consisting of community-based lay and professional organizations in this area, the Cancer Coordinating Council will attempt to promote, facilitate, and coordinate cancer control programs in the region. Additionally, the CCCMW will be responsible for identifying areas of unmet needs as they pertain to cancer programming and it will act to meet those needs by recommending outreach projects to be conducted by participating institutions or by separately funded projects under the sponsorship of the CCCMW.

To further accomplish its purpose in 1979 the Outreach Program will conduct specific cancer control activities in the areas of Communications, Health Education, Planning and Evaluation, and Epidemiology. All of these activities are designed to ultimately produce a comprehensive cancer control program for Metropolitan Washington.

CANCER CENTER SUPPORT (CORE) GRANT

E.L. Wynder, American Health Foundation Inc., *320 E. 43rd St., New York, New York* 10017 (P30 CA 17613-05)

The American Health Foundation, with its well established and functional interdisciplinary team, expects to have continued impact on the solution of major environmental cancer problems ranging from specific items with widespread usage such as tobacco and cosmetics, and food products such as saccharin, to hazards affecting limited groups like shipyard workers. We also hope to continue to make fundamental contributions to the understanding on the mechanisms by which various environmental forces relate to human cancers through in vitro and in vivo studies. Our major efforts will continue to be a comprehensive program of research leading to the prevention of major human cancers.

ADMINISTRATION OF NATIONAL PANCREATIC CANCER PROJECT

I. Cohn, Louisiana State University, Medical Center, School of Medicine, Dept. of Surgery, *1542 Tulane Ave., New Orleans, Louisiana* 70112 (R26 CA 17500-06)

This renewal application proposes continuation of the National Pancreatic Cancer Project for a period of five years (1980-1984). It is requested that Louisiana State University School of Medicine remain the Headquarters institution with Isidore Cohn, Jr., M.D., Professor and Chairman, Department of Surgery, as Project Director.

Since its founding in January, 1975, the Project has been increasingly active in the stimulation and coordination of research efforts in the field of pancreatic cancer. The Project Plan will continue to be directed toward reduction of the incidence, morbidity and mortality of the disease through basic and clinical research in the areas of epidemiology, experimental biology, diagnosis, immunology, pathology and treatment. At present, the search for improved methods of treatment is identified as the first priority of the Project's research plan.

The National Pancreatic Cancer Project will continue its effective use of the NIH system of peer review of grant applications with the assistance and cooperation of its Pancreatic Review Subcommittee, comprised of scientists who are especially interested and qualified in the study of pancreatic disease. The Headquarters staff will assist this body of scientists in carrying out their duties and will coordinate the daily activities of the Project.

FOLLOW-UP STUDY OF IRRADIATED TINEA CAPITIS CASES

R.E. Albert, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016 (R01 CA 17188-03S2)

The purpose of the proposed research is to further characterize the nature and magnitude of late radiation damage due to X-ray therapy for ringworm of the scalp. A third survey of a population of 3,600 children with tinea capitis in the period 1940 to 1959, 2,200 of whom received X-ray therapy, is in progress. The survey consists of a health questionnaire completed by subjects with diagnostic confirmation of tumors and other significant conditions from medical sources. A clinical evaluation of a subsample of irradiated and unirradiated subjects will be undertaken, which will include tumor, hair, visual and auditory examinations. Major health effects will be related to dose and temporal patterns of occurrence.

USC CANCER CENTER EPIDEMIOLOGY AND BIOSTATISTICS UNIT

B.E. Henderson, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (P01 CA 17054-04A1)

This proposal requests continuing support for an Epidemiology and Biostatistics Research Program as a major component of the Los Angeles County/University of Southern California Cancer Center.

A large part of the research effort is the Cancer Surveillance Program (CSP) headed by Dr. Thomas Mack. The CSP provides prompt reporting and detailed demographic data on virtually all new cancer cases diagnosed in the entire population of seven million residents of Los Angeles County. A major function of the CSP is to provide cancer patient identification for etiologic field studies. The descriptive information from the CSP provides additional etiological clues and a system for checking the consistency of suggested causal associations with cancer rates in the population. The CSP also identifies high risk program targets, and constitutes a cancer research organization with a presence in each of the county's diagnostic facilities.

The Biostatistics Unit headed by Dr. Malcolm Pike supports some field staff as well as the analytic component of our field studies. Development of new statistical methods to deal with these field studies and other cancer related studies is also undertaken by this unit. Funds for most field studies are currently being obtained from several research contracts and grants. The desirability of having the capability of making a rapid and flexible response to newly suggested hypotheses demands some field staff without unalterable commitments.

HUMAN CANCER SEROLOGY

L.J. Old, Sloan Kettering Inst. for Cancer Research, *410 E. 68th St., New York, New York* 10021 (P01 CA 19765-03S1)

The goals of the Human Cancer Serology Program are: (1) Determine the role of viruses in the etiology of human cancer; (2) detect and analyze humoral immune reactions to cancer cells in patients with

cancer; (3) identify characteristic human tumor antigens with heteroimmune sera for the purpose of developing immunodiagnostic methods for early cancer detection. In approaching these goals, a group with expertise in the techniques of virology, serology, cell culture and biochemistry has defined seven specific projects. They are: (a) Serovirological studies of Kaposi's sarcoma, with emphasis on the suspected etiological role of cytomegalovirus; (b) search for interspecies antigens of mammalian leukemia-sarcoma viruses (oncornaviruses) in human cancer with immunofluorescence, absorption, and radioimmunoassay techniques; (c) preparation of serological reagents to human papovaviruses to determine whether these viruses are involved in the etiology of tumors of the CNS and urinary tract, as well as of tumors occurring in patients with primary immunodeficiency disease; (d) definition of a group-antigen of herpesvirus, its serological relatedness to mammalian oncornaviruses, and its possible occurrence in human cancer; (e) detection and analysis of humoral immune reactions to cell surface antigens of melanoma and renal cancer; (f) analysis of a new intracellular antigen (P5NA) of osteogenic sarcoma, and seroepidemiology of the P5NA antigen and antibody in normal individuals and in patients with cancer and other diseases; and (g) characterization of the antigens of ovarian cancer with heteroimmune sera, and determination of the frequency and biochemical nature of anomalous blood group-like antigens in ovarian cancer.

These studies are intended to provide fresh insights into the etiology, diagnosis, and therapy of human cancer.

HUMAN RADIATION CARCINOGENESIS STUDY

E.D. Woodard, University of Rochester, School of Medicine & Dentistry, Dept. of Radiology, *601 Elmwood Ave., Rochester, New York* 14627 (R18 CA 19764-03)

This represents a continuation of a long-term prospective study of radiation-induced carcinogenesis in three human populations: the first, persons who were treated in infancy with x-rays for alleged enlargement of the thymus gland; the second, women who received x-ray treatments to the breasts for postpartum mastitis; and the third, persons given x-ray and/or radium treatments to the head in early childhood for lymphoid hyperplasia of the nasopharynx. Health data are collected by mail questionnaires from treated persons and from their untreated sibling controls. Significant reported illnesses are verified through the attending physician and hospital. Histological reviews are performed on slides from tumors of primary interest in the studies.

A program of mammographic-thermographic screening of the women who received breast irradiation will be repeated. In addition, a sample of their untreated sisters (controls) who meet NCI recommended eligibility requirements for mammographic-thermographic screening will also be examined.

The objectives of the program are (1) to determine the qualitative nature and quantitative risk of radiation-induced neoplastic disease and of conditions with abnormal immunological features, and (2) to effect, by screening, the early diagnosis and treatment of breast cancer in a high-risk population.

CANCER IN PARENTS OF CONGENITALLY DEFECTIVE CHILDREN

D.T. Janerich, State Bureau of Cancer Control, *Empire State Plaza, Tower Bldg. Rm. 565, Albany, New York* 12237 (R01 CA 19564-03)

This descriptive epidemiological study is designed to investigate unusual familial coexistence of cancer and congenital neural tube closure defects (anencephaly and spina bifida). A retrospective epidemiological cohort approach will be used to determine whether conceiving a child with anencephaly or spina bifida has any relationship to the parents' subsequent risk of developing cancer. Evidence of a positive association would enhance our understanding of the etiology of cancer in humans, and could have immediate value in developing preventive measures to reduce cancer mortality through early detection of high risk individuals. We are proposing to study the most direct and epidemiologically useful aspect of unusual familial coexistence between cancer and congenital malformations. There are two underlying biological bases for this study. First, the fact that carcinogenesis and teratogenesis can sometimes be caused by the same agents (i.e., radiation), as well as the fact that carcinogens can sometimes act through teratogenic-like mechanisms (i.e., diethylstilbestrol). Second, the limited available data on familial coexistence of cancer and congenital malformation theoretically implies that the control of abnormal embryological development and the control of malignant cellular change are genetically related. If so, it is likely that evidence of the association can be detected in these family studies.

CLINICAL CANCER

A.L. Watne, West Virginia University, School of Medicine, Dept. of Surgery, *Morgantown, West Virginia* 26506 (R25 CA 19530-03)

The objectives of the Clinical Cancer Education Program include acquiring an understanding of cancer biology, epidemiology, detection, diagnosis, treatment and control along with establishing attitudes for continuing education about cancer and concepts of multidisciplinary care for the cancer patient.

The methods include a Basic Cancer Course for clinical assistants utilizing a systems approach to curriculum and design, a continuing education program in cancer involving all phases of work each year, senior oncology electives to emphasize the multidisciplinary aspects of cancer care and comprehensive multidiscipline clinical associate program emphasizing care for the complex cancer patient.

The evaluation for the four components of the program will be developing process evaluating changes in student behavior in both the cognitive and affective domains.

CASE CONTROL STUDY OF CARCINOMA OF THE ESOPHAGUS

T.M. Mack, University of Southern California, School of Medicine, Dept. of Community Medicine & Public Health, *2025 Zonal Ave., Los Angeles, California* 90033 (R01 CA 19496-04)

The study proposed is a large case control study to be performed prospectively in Los Angeles County. It has been designed to permit simultaneous examination of multiple antecedent risk factors.

Cases with cancer of the esophagus will be identified by the LAC/USC Cancer Surveillance Program. A questionnaire has been designed to obtain data on environmental exposures - tobacco and alcohol consumption, diet, occupation and medical history and treatment. It will be administered to both cases and neighborhood controls as soon as possible after the cases have been diagnosed. Standard matched pair analyses of multiple variables will be performed on the data from the questionnaire.

STUDIES OF THE HISTOGENESIS OF PANCREATIC CARCINOMA

D.S. Longnecker, Dartmouth College, School of Medicine, Dept. of Pathology, *P.O. Box 833, Hanover, New Hampshire* 03755 (R26 CA 19410-05)

The histogenesis of carcinoma of the pancreas will be studied and compared in man and experimental animals. The epidemiology of association of putative preneoplastic lesions of human pancreas with risk factors will be analyzed to assess the significance of focal acinar cell dysplasia in human pancreas. One hundred human pancreatic cancers will be studied by electron microscopy to search for evidence of ductal vs. acinar cell origin. The reversibility of carcinogen-induced foci of atypical acinar cells will be assessed in rats. One hundred azaserine-induced pancreatic carcinomas will be classified histologically and compared to the histologic types of human pancreatic cancer. The histogenesis and histologic types of pancreatic cancers will be studied in a single species which responds to carcinogens which are reported to affect acinar cells, i.e., azaserine or N delta-(N-methyl-N-nitrosocarbamoyl)-L-ornithine, and ductal cells, i.e., N-nitrosobis(2-oxopropyl)amine. Species to be used for these studies are Mastomys natalensis and the Syrian golden hamster. RIA and immunohistochemical demonstration of pancreatic trypsin inhibitors will be employed to study their possible role in inhibition of carcinogenesis in pancreatic acinar cells. The response of transplantable acinar cell and ductal carcinomas of the pancreas to amino acid chemotherapeutic agents will be studied in rats and hamsters.

GENETIC EPIDEMIOLOGY OF CANCER

K.M. Weiss, University of Texas, Health Science Center at Houston, Graduate School of Biomedical Sciences, *P.O. Box 20334, Houston, Texas* 77025 (R01 CA 19311-03)

Genealogies from the Mexican-American city of Laredo, Texas are compiled from civil and church birth, death, and marriage records. The city will thus be ascertained more or less totally and without any bias relative to biomedical studies. Cause of death will be mapped onto these genealogies. The genealogies will be examined stastically to determine whether, and to what extent, there is familial clustering of death due to cancer in general or cancer at varius organ sites. Demographic data, including fertility, will be applied both to the assembly, by computer, of genealogies and to the analysis of the cause of death patterns. By parameterizing death rates by age, we hope to express this risk in terms which are meaningfully related to underlying biological processes related to human aging and to the causation of cancer itself. Competing causes of death will be taken into account in our analysis, which will also test for first-order environmental effects by examining the genalogies for cancer clustering when unrelated individuals (i.e. spouses) have been substituted into them. Our genealogies reach back to the 18th century, with cause of death information beginning about 1900.

SURVEILLANCE FOR DRUGS THAT MAY BE CARCINOGENIC

G.D. Friedman, Kaiser Foundation Research Inst., *1956 Webster St., Room 310 B, Oakland, California* 94612 (R01 CA 19939-04)

The objective of this project is to evaluate medicinal drugs for possible carcinogenic effects. Screening studies will be accomplished by following up a group of 149,000 patients in a prepaid health plan who had computer-sorted pharmacy records of prescriptions dispensed from July, 1969 through August, 1973. Increased incidence of any cancer among users of a drug as compared to expected incidence derived from the entire cohort, will indicate a drug-cancer association to be evaluated further. More definitive study of hypothesized drug-cancer relationships will be accomplished by case-control studies using the patients' longitudinal medical records.

ONCOLOGY CENTER SUPPORT GRANT

A.H. Owens, Johns Hopkins University, School of Medicine, Dept. of Oncology, *725 N. Wolfe St., Baltimore, Maryland* 21205 (P30 CA 06973-16)

The Oncology Center serves as a resource dedicated to research and education in cancer and related disorders. Special efforts are made to apply new knowledge to improve the care of cancer patients and to prevent the occurrence of neoplastic diseases. 1. Research: In order to increase present understanding of human neoplasias and their effective clinical management, seven disease-oriented programs have been organized (leukemia, lymphoma, plasma cell dyscrasias, childhood neoplasia, breast cancer, small cell cancer of the lung, and sarcomas) to interact with seven laboratories (Transplantation Biology, Cell Proliferation, Immunochemistry, Cell Biology, Biochemical Virology, Pharmacology, and Cell Structure and Function). 2. Education: Programs of instruction in oncology are available to students at all levels. Special emphasis is placed on postgraduate education of physicians and laboratory scientists. 3. Clinical Services: Special consultation and treatment facilities are available for multidisciplinary programs, including an advanced radiation therapy unit. 4. Community Outreach: A network for cancer patient care and continuing education is being developed with regional hospitals and physicians. 5. National Cancer Program: This Center is linked with others to contribute toward the National Cancer Program.

GENETIC STUDIES OF HERITABLE COLORECTAL CANCER

B.S. Danes, Cornell University, Medical Center, Cornell Medical College, Dept. of Medicine, *1300 York Ave., New York, New York* 10021 (R26 CA 15973-05)

The identification of individuals at high risk for the development of large bowel cancer prior to clinical symptoms and the incidence/hazards of mutagenesis and transformation that their somatic cells are at risk for are the dual aims of this research proposal. These two aims are subdivided into 4 working objectives: (1) to identify a culture phenotype which consistently and reliably reflects the presence of a germinal mutation in a cultured somatic cell from individuals at risk for a hereditary colorectal cancer and to use this culture phenotype to determine how this mutation (a) affects cell function and (b) is expressed in tissue specificity, a property that all hereditary tumors appear to possess; (2) to develop a model system for testing the two-step hypothesis of carcinogenesis; (3) to study the mutagenesis in cell populations with and without known germinal mutations for colorectal cancer; (4) to study transformation in such genotypically abnormal cells in an attempt to evaluate the risk individuals with such genotypes run in exposure to known environmental agents inducing mutagenesis and transformation. Cell culture studies will be based on the family as the study unit.

CANCER CENTER SUPPORT GRANT (COMPREHENSIVE)

W.B. Hutchinson, Fred Hutchinson Cancer Research Center, *1124 Columbia St., Seattle, Washington* 98104 (P30 CA 15704-06)

The Fred Hutchinson Cancer Research Center is implementing the goals and objectives of the National Cancer Act of 1971 by encouraging and engaging in basic and clinical research directed toward the prevention, detection, diagnosis and treatment of cancer in man and by aiding in the development and coordination of both the professional and lay education by serving as a focal point for the demonstration and organization of methods for improving the health care of the cancer patient in the Pacific Northwest. The Center serves not only as an architectural entity but also as an institutional and a programmatic focus for these activities. Significant programs in basic and clinical cancer research and in the provision of health care for the cancer patient exist within the Pacific Northwest which includes the WAMI area (Washington, Alaska, Montana, Idaho) and the State of Oregon. Located within the Center are programs in tumor immunology, biochemical oncology directed toward tumor cell membranes, chemical carcinogenesis, related oncologic organic chemistry, medical oncology, viral oncology, basic immunology and genetics. In the extramural area studies in biostatistics/epidemiology, library services and information have been implemented. Affiliated programs in rehabilitation, regional cooperative cancer studies, therapeutic radiology, pediatric oncology and cancer detection are assisted by the Center.

CANCER EPIDEMIOLOGY AND PREVENTION RESEARCH CENTER

B. MacMahon, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115 (P01 CA 06373-18)

The proposed research is a program of studies of the epidemiology of the major human cancers, with the ultimate goal of developing knowledge which will lead to the prevention of these diseases.

The focus of the research will be on cancer of the breast, especially in relation to patterns of metabolism of endogenous estrogens in young adult life, oral contraceptive use, and other hormonal factors. Emphasis is on the detection of early markers characteristic of increased risk of cancer of the breast, prostate and colon. Other studies are on Hodgkin's disease, bladder cancer, cancer of the pancreas, and multiple myeloma. In addition, we plan to continue to develop epidemiologic methods, particularly those methods for application in the field of cancer epidemiology. Methodologic areas of investigation include life table analysis of survival data and various aspects of significance testing and interval estimation.

Using a variety of resources, the studies will employ different epidemiologic approaches including case-control studies, prospective cohort studies, and review of existing data in the Department. Many of these studies are developed on the basis of studies designed and completed in earlier years; some studies are supported for planning phase only; and others are continuations of ongoing data collection and analysis.

SOUTHWEST ONCOLOGY GROUP (PEDIATRIC)

D.J. Fernbach, Baylor College of Medicine, School of Medicine, Dept. of Pediatrics, *1200 Moursund Ave., Houston, Texas* 77025 (R10 CA 03161-23)

The year 1979 is the 22nd year that the Department of Pediatrics, Baylor College of Medicine, has participated in the activities of the Southwest Oncology Group (SWOG). The initial purpose of this group was to develop better methods of treatment for the control or cure of cancer in children. If a cure cannot be achieved, therapy is directed toward palliation of the disease, its consequences, prolonged survival, and perhaps most importantly, quality of survival. During the past few years multidisciplinary treatment programs have been developed and greater emphasis has been directed toward the etiology and pathophysiology of these diseases. This unit participates in all activities of the Pediatric Division. These activities include: Phase I studies of new chemical or biological agents; Phase II studies utilizing single or multiple agents in various disease categories; and Phase III studies, most of which are multidisciplinary, striving to determine the best combinations of therapy for control or cure of childhood cancer. Studies of the immunologic defects associated with various malignancies and immunotherapy directed toward eradication of various malignancies have been enlarged both within the Group and independently within this unit. Other areas of investigation relate to the epidemiology of malignant disease, the natural history of individual neoplastic disorders, and evaluations of methods to control the complications resulting from the disease or therapies. Particular emphasis has been given to determining prognostic factors and toward stratifying clinical case material accordingly in order to improve the basic study design. The biostatisticians have long been an integral part of the group's chemotherapy studies. Their role has been expanded to involve all multidisciplinary activities. Approximately 5 years ago the disciplines - radiotherapy, pathology, and surgery - began active participation in all group studies. During the past 2 years the representatives from these disciplines have provided invaluable expertise in their specialties from the time of inception of all appropriate studies.

CANCER RISK AFTER IRRADIATION AND/OR CHEMOTHERAPY

D. Schottenfeld, Memorial Hospital for Cancer & Allied Diseases, *1275 York Ave., New York, New York* 10021 (R01 CA 17028-04)

The primary objective of this research is to test the hypothesis of whether Hodgkin's disease patients are exposed to an increased risk of the development of subsequent multiple primaries by the various intensities and/or ordered sequences of radiation therapy and chemotherapy (given singly or in combined regimens) which have served as therapeutic approaches to the management of Hodgkin's disease. Histopathologic classification of Hodgkin's disease and the extent of disease involvement at the time of first treatment will be studied in relation to the patterns of second primary cancer occurrence by organ site and histopathology.

DIET, FLORA AND COLON TUMORIGENESIS

S.A. Broitman, Boston University, School of Medicine, Dept. of Microbiology, *80 E. Concord St., Boston, Massachusetts* 02215 (R26 CA 16750-05)

The long-term objective of this laboratory work is to identify nutritional factors which contribute to the high incidence of colon cancer in Western culture. In this proposal, studies are focused on the role of dietary and endogenous cholesterol and its metabolites in the gut lumen in large bowel tumorigenesis in an experimental animal. Continuing studies are planned on the interrelationship between dietary polyunsaturated fat and saturated fat, particularly as it relates to the disbursement of cholesterol systemically and/or enterally. Various nutritional regimens containing 20% fat with and without cholesterol are fed to rats given an indirect acting carcinogen, 1,2 dimethylhydrazine (s.c. or orally), or a direct acting carcinogen, N-methyl-N'-nitro-N-nitroguanidine (intrarectally). These diets will allow an evaluation of the interrelationships between the quality of dietary fat, the enteral excretion of cholesterol and its metabolites and large bowel tumorigenesis. Effects of cholesterol and its metabolites will be evaluated in terms of tumor number, histological types and location, latency period and tumor incidence. An assessment of fecal excretion of neutral and acid sterols as well as fecal 7-alpha-dehydroxylase and cholesterol dehydrogenase activities occurring in rats fed the various dietary regimes will permit correlative studies with large bowel tumorigenesis. Using the Ames Salmonella/microsomal assay for mutagens/carcinogens, various fecal sterol metabolites will be evaluated to pinpoint those componets which may be carcinogenic or cocarcinogenic for further testing. These studies should provide: 1) a better understanding of the relationships between nutrition, microflora and colonic cancer; 2) additional information concerning the nutritional linkage between coronary heart disease and colon cancer and 3) additional guidelines for studies in human nutrition aimed at decreasing the incidence of colon cancer.

CANCER INCIDENCE AND RISK FACTORS BY KINSHIP

M.H. Skolnick, LDS Hospital, Dept. of Medical Biophysics & Computing, *325 8th Ave., Salt Lake City, Utah* 84103 (R01 CA 16573-06)

From a Utah Mormon genealogy of more than one million individuals linked to a Cancer Registry of more than 30,000 cases, we will: (1) Determine the genetic contributions to the occurrence of cancer for specific sites in a general population, including the estimation of heritability for specific age-sex categories. (2) Fit specific genetic models which will best explain any observed patterns of the occurrence of specific cancer sites or groups found to cluster in large pedigrees. Components of the models will include modes of inheritance and factors which influence gene expression (such as age, sex, and pertinent environmental factors when known). In-depth pedigree and chromosomal marker studies provide important additional data for this analysis. (3) Investigate the potential association of a large number of immunologic, biochemical, and anthropomorphic genetic markers to various forms of cancer in an effort to characterize these traits for people who are at high genetic risk for acquiring the disease and then attempt to use this information for early detection or prevention of the cancer.

CANCER CENTER SUPPORT GRANT

R.A. Cooper, University of Pennsylvania, School of Medicine, Dept. of Medicine, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (P30 CA 16520-05)

The University of Pennsylvania Cancer Center (UPCC) study is a multidisciplinary program in cancer research, education and clinical care. Based in the School of Medicine, it involves faculty from many schools of the University. The UPCC is one component of the Fox Chase-U. of P. Comprehensive Cancer Center. Interdisciplinary clinical research programs of the UPCC exist in hemotology-oncology, radiation therapy, surgical oncology and gynecologic oncology. A multidisciplinary program has been established in head and neck tumors, and similar programs are developing in neuro-oncology and urologic cancer. Clinical research programs utilize the shared resources of the Center's inpatient Oncology Study Unit, Clinical Trials Data Center, Pharmacology Core and Nutrition Support Service. Interdisciplinary fundamental research programs exist in immunobiology, cell biology, virology, genetics, and radiobiology. Program development involving tumor immunology and bone marrow culture is planned. Fundamental research programs utilize the shared resources of an animal breeding colony and tissue culture core, and they are strengthened by a Visiting Scientist Program. Acquisition of a fluorescence activated cell sorter is also planned. The Center's Epidemiology and Statistics Unit includes epidemiologic studies of occupational carcinogenesis and biostatistical research. The Unit established a biostatistics shared resource for the UPCC and a patient data system compatible with the CCPDS. A multidisciplinary Psychosocial Program, recently established, addresses needs in areas of research, service and education. Other Educational Programs have been established as well, and the UPCC provides a range of opportunities for medical and nursing students, fellows, practicing physicians and other health professionals. The UPCC Cancer Control Program extends to community hospitals in Pennsylvania and New Jersey. An information letter, Cancer Update, provides UPCC news and cancer education for Center members and other professionals who relate to the UPCC.

2.0582,

HERPESVIRUS INFECTIONS IN HIGH RISK CANCER GROUPS

D.W. Reynolds, University of Alabama in Birmingham, School of Medicine, Dept. of Pediatrics, *1919 7th Ave. S., Birmingham, Alabama* 35233 (R01 CA 16424-05)

This project involves study of the natural history of herpesvirus infections in renal transplant patients and low income urban females, two target populations with increased risk of cancer. In renal transplant patients the natural history of cytomegalovirus (CMV), herpes simplex virus (HSV), Epstein-Barr virus (EBV), and varicella zoster virus (VZV) infections will be investigated. In the low income young women, the natural history of genital HSV and CMV infections will be studied. In both of these populations, particular attention will be payed to factors which lead to reactivation of apparently latent infections. In renal transplant patients the effect of immunosuppression and histocompatability on specific humoral and cellular immunity, viral excretion, and development of clinical manifestations of viral infection will be examined. Young women with cervical CMV and HSV excretions will be characterized by frequency of recurrences in relation to age, parity, presence of infection with more than one viral agent, and cervical cytology.

In both the renal transplant patients and in the normal low income women, an attempt will be made to correlate natural history of viral infections with development of malignancies, should any occur. Children born with congenital CMV who are born to young women in this study will also be compared to uninfected controls with regard to incidence of malignancy. In the case of transplant patients and young women the majority of subjects are expected to be infected with more than one herpesvirus; thus it is unlikely that any etiologic association between malignancy and viral infection can be established through epidemiologic study.

METABOLIC EPIDEMIOLOGY OF COLON CANCER

B.S. Reddy, American Health Foundation Inc., Naylor Dana Inst. for Disease Prevention, *Hammond House Rd., Valhalla, New York* 10595 (R26 CA 16382-05)

OBJECTIVE: The overall objective of the proposed research is to: (a) acquire significant information on the mechanisms related to, and the role played by: dietary components, intestinal microflora and their metabolites on the etiology of colon cancer in man, (b) identify specific environmental and dietary components that either directly cause colon cancer or indirectly promote the formation and development of colon neoplasms, and (c) develop key biochemical and/or microbial indicators which distinguish low- and high-risk populations for colon cancer.

APPROACH: The proposed study will determine: the fecal cholesterol and bile acid metabolites and fecal bacterial 7 alpha-dehydroxylase, cholesterol dehydrogenase and nuclear dehydrogenase activities and fecal bacterial transnitrozation reaction in members of high-risk cancer families, patients with familial polyposis and healthy controls consuming a mixed-Western diet. We also continue the present study in determining the metabolic activity of fecal microflora (above enzyme parameters) in patients with colon cancer and adenomatous polyps to permit an evaluation of these discriminants for colon cancer. In addition, we propose to isolate and identify the mutagens (presumptive carcinogens) in the feces of above study populations.

STUDIES ON THE PATHOGENESIS AND TREATMENT OF BURKITT'S LYMPHOMA IN GHANA

R.J. Biggar, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Clinical Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-CP-04851-04-LVC)

Burkitt's lymphoma (BL) is of great importance to human tumor studies because of the epidemiologic, virologic and immunologic evidence that it is virus induced. The Burkitt Tumor Project (BTP) in Accra, Ghana, is an attempt to systematically study a series of BL patients in order to clarify the pathogenesis of the disease and develop better methods of control. Current studies are concentrated on the pathogenesis of EBV infection in newborns, and the comparison of the epidemiology of EBV and BL in West Africa (Ghana) with the reported pattern in East Africa. In addition, the project is looking at humoral and cell-mediated immunity to EBV and tumor-associated antigens as diagnostic and prognostic tools in BL, and investigating the role of malaria as a cofactor in disease etiology.

METROPOLITAN ATLANTA SEER PROGRAM

M.A. Child, Emory University, School of Medicine, Dept. of Medicine, *1364 Clifton Rd. N.E., Atlanta, Georgia* 30322

As a participant in the SEER Program, this Contractor is to provide data for incidence and end results reporting on all cancers diagnosed among residents of the Metropolitan Atlanta area. During the initial contract period, the Contractor will undertake the planning and development of data acquisition, coding, processing, and editing necessary to the implementation of the SEER Program in the Atlanta Metropolitan area. During the second contract period, the reporting system will concentrate on cases diagnosed during 1976 and may, as time allows, pick up cases diagnosed during 1972-1975 so that continuous incidence data from 1969 forward will be available by virtue of Atlanta's participation in the Third National Cancer Survey. The data are to be recorded in accordance with rules agreed upon by SEER Program participants and will periodically be submitted to the Biometry Branch, NCI, for analysis.

A PROSPECTIVE STUDY OF LYMPHOID TISSUES IN NEOPLASIA

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201 (R01 CA 25020-02)

A prospective epidemiological study on subsequent cancer risk, by site, among cohorts of individuals undergoing tonsillectomy/adenoidectomy and/or appendectomy between 1925 and 1936 is continuing. Because a large proportion of the cohorts can now be expected to be deceased, a reliable and valid estimate of specific cancer risks according to type of lymphoid tissue surgery is expected to be generated. At present, major efforts are continuing to trace the cohorts as completely as possible to death or to survival as of a recent date. Also continuing is a preliminary analysis, among individuals already traced, of specific cancer risks. The prospective design of this study permits the estimation of true cancer risks, as opposed to the relative risks or odds ratios which must be relied upon in retrospective studies.

IMMUNOBLASTIC LYMPHADENOPATHY AND HISTIOCYTIC LYMPHOMA

R.K. Ross, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033 (R01 CA 24082-02)

We are studying the epidemiology of histiocytic lymphomas, and a possibly related disease entity, immunoblastic lymphadenopathy (IBL), in Los Angeles County. The study is designed to test for multiple antecedent risk factors for these diseases, with special emphasis on therapeutic agents previously implicated. The study is a two-part case-control study. The case group will consist of 100 cases of histiocytic lymphoma identified by the Los Angeles County/USC Center Surveillance Program, plus 50 cases of immunoblastic lymphadenopathy identified by the pathologic consulting service of Dr. Robert Lukes. Data will be obtained by interviews conducted by a trained nurse epidemiologist. Questionnaire information will focus on therapeutic history, environmental exposures at work and at home, allergic and other possible relevant past disease history, and family history of tumors. Medication history will be validated by contacting personal dentists and physicians of cases and controls.

In addition, venous blood specimens will be obtained on a group of IBL and histiocytic lymphoma cases and controls in order to help characterize the immune responses and assist in determining the affected cell types of these patients.

ETIOLOGY AND EPIDEMIOLOGY OF HUMAN CANCER

M.B. Gardner, University of Southern California, School of Medicine, Dept. of Pathology, *2025 Zonal Ave., Los Angeles, California* 90033

Etiology and Epidemiology of Human Cancer. This is a multi-faceted study to determine the contributions of genetic susceptibilities, 'oncogenic' RNA and DNA viruses, and the influence of environmental carcinogens to the etiology of cancer. Approaches include search for and isolation of etiologic viral agents or evidence of viral antigenic activity, and the development of vaccines to protect against natural and induced cancers.

DETROIT SSMA POPULATION-BASED CANCER REGISTRY

M.J. Brennan, Michigan Cancer Foundation, *110 E. Warren St., Detroit, Michigan* 48201

Follow-up of all patients to determine their vital status will be accomplished on all registry cases to provide information on the end results of cancer treatment. The objectives are: Provide to NCI, in accordance with instructions from the Project Officer, computer tapes with data obtained from both incidence and end results reporting systems. Maintain a core staff, including professional and technical people, to complete the remaining tasks for the Third National Cancer Survey. Develop plans for a core staff, including both professional and technical people, who would facilitate planning and implementation of ad hoc studies. Produce a manual setting forth the activities and responsibilities of all registry personnel and a description of the procedures that will be followed for each specific activity such as abstracting, case-finding, editing, quality control, etc.

DEMOGRAPHIC CANCER RESEARCH PROGRAM IN HAWAII

L.H. Piette, University of Hawaii System, Manoa Campus, John A. Burns School of Medicine, Dept. of Biochemistry & Biophysics, *2444 Dole St., Pacific Biomedical Res. Ctr., Honolulu, Hawaii* 96822

The general plan of the Demographic Research Program is to: develop demographic/epidemiologic programs in collaboration with the Basic Science and Clinical Research Programs of the Cancer Center of Hawaii; work closely with Dr. Stemmermann on his Japan-Hawaii Cancer Study to fully utilize those data; and assist basic and clinical cancer research programs as well as all cancer control programs developed in the Cancer Center and in the community by providing expertise and personnel to assist in demographic/epidemiologic study designs, study surveillance, and study evaluation. Case-control interview work on Japanese migrant studies is included in this program.

IMMUNODEFICIENCY-CANCER REGISTRY

J.H. Kersey, University of Minnesota, Minneapolis Campus, School of Medicine, Dept. of Laboratory Medicine & Pathology, *1305 Mayo, Minneapolis, Minnesota* 55455

Upon consultation between the members of the Epidemiology Branch of NCI and the members of the Immunodeficiency Registry, it was decided that a collaborative program between these two parties should be developed. The goals of this collaborative program would be as follows: to continue the registry's activities as outlined above; to explore in feasibility study two additional activities; and to conduct these activities, if deemed feasible. The two additional activities are: to determine better estimates than are currently available of the prevalence of immunodeficiency syntromes by types, age, and sex in general population (the feasiblity of an incidence survey would also be explored at this time); and to conduct a case-control study of the clinical, demographic, and laboratory characteristics of immunodeficient patients who developed a malignancy vs. those who didn't.

MALE ROLE IN CERVICAL CANCER

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Social & Preventive Medicine, *655 W. Baltimore St., Baltimore, Maryland* 21201 (R01 CA 25019-02)

Studies utilizing a variety of methods suggest that the male sex partner may play a role in the etiology of cervical cancer. Demographic analyses reveal higher cervical mortality rates among married than among single women or virgins. A possible association between penile and cervical cancer has been demonstrated. Considerable evidence has accumulated on the relationship between cervical cancer and the venerally transmitted genital herpesvirus, HSV-2. The results of these studies have increased the likelihood of a significant male role in cervical carcinogenesis.

Our ongoing study begins with the identificatin of a large group of women who had cervical cancer in greater Baltimore during the past 20 years. The husbands of these women are investigated to the extent of identifying all their previous and subsequent wives ('case' wives). A random sample of 'control' wives, similar to the 'case' wives in demographic and marital characteristics is then selected. The cohorts of 'case' and 'control' wives are traced prospectively to death or survival as of a recent time. The ultimate risk of cervical neoplasia among the two cohorts is compared, utilizing actuarial techniques. This approach affords a direct test of the role of any venereally transmitted male factor in cervical cancer, whether it be viral, chemical or other.

A PROSPECTIVE STUDY OF CANCER RISK IN TUBERCULOSIS

I.I. Kessler, University of Maryland, Baltimore Professional Schools, School of Medicine, Dept. of Epidemiology, *655 W. Baltimore St., Baltimore, Maryland* 21201 (R01 CA 25018-02)

Interest in the hypothesized association between tuberculosis and cancer has been intensified by studies demonstrating that tubercle bacilli (i.e., BCG) potentiates host immune responses to cancer challenge. Recent experiments in man suggest that BCG acts not only to evoke non-specific cell-mediated immunity but also to increase host resistance against specific tumors such as melanoma, sarcoma and breast cancer.

In view of the above, a type of natural experiment in cancer prevention is underway. A large cohort of tuberculosis patients is being followed prospectively through time to death or survival as of December 31, 1974. The outcome variables of interest are cancer mortality and morbidity. Observed cancer risks will be compared with those of the general population similar in age, sex and race. Additional analyses will focus upon cancer risk according to clinical severity of tuberculosis, with adjustment for smoking habits. Consideration will also be given to cancer risks among close family members as a further test of the antitumor immunogenicity of exposure to tuberculosis.

The prospective design of this study is relatively free of biases inherent in earlier efforts. This will also make possible the study of the association between tuberculosis and all types of cancer. A significant relationship between the two could suggest the possibility of BCG or tuberculin vaccination as a cancer preventive.

2.0603,

BREAST PARENCHYMAL PATTERNS AND BREAST CANCER RISK

P. Cole, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115 (R01 CA 24797-01)

The principal objectives of this study are: a. To evaluate the relationship between specific mammographic parenchymal characteristics and the incidence of female breast cancer; b. to evaluate the relationship between mammographic parenchymal characteristics and risk factors for breast cancer. Other objectives are to identify histologic correlates of mammographic parenchymal characteristics and to evaluate both right-left concordance of parenchymal pattern, and observer reliability in the assessment of these patterns.

All women (including 800 new cases of breast cancer) having xeromammograms in any of seven collaborating radiology units during 1978 or 1979 will be enrolled. Information on status with respect to breast cancer risk factors, parenchymal pattern (Wolfe's classification) and pathologic diagnosis will be obtained from the subjects' radiology records. From this series, 400 cases and 800 controls, equally divided between the age groups less than 55 and 55-74, will be selected for a detailed 'blind' review of both xeromammogram and histologic slides. For women in each age group relative risk of breast cancer according to parenchymal pattern, with the N1 pattern as the referent, will be estimated. If necessary, these estimates will be corrected for confounding by other risk indicators. Possible interactions will also be quantified.

2.0604,

CANCER STUDIES IN WASHINGTON COUNTY, MARYLAND

G.W. Comstock, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 CA 24758-02)

The proposed project has several related objectives. First is to maintain a serum-bank and cancer registry as a facility for studies of the epidemiology of major cancers, with special reference to serum factors antedating the diagnosis with serum assays of matched control specimens drawn at the same time, and also comparing serum assays of cancer cases before and after diagnosis which will identify risk factors, thereby adding useful knowledge of cancer etiology and helping to focus preventive practices. The second objective is to compare serum estrogen and androgen levels in serum specimens drawn in 1974 from breast cancer cases diagnosed since that time and their matched controls. The control experience will also be useful to see if serum hormone levels are related to other breast cancer risk factors. An additional study will measure disability and mood among breast cancer cases and age-matched controls. This will confirm and amplify a preliminary study that indicated that disability and mood changes observed in women several years after mastectomy resulted from age and not from their diagnosis or treatment.

A fourth objective is to study serum estrogen and androgen levels among groups of postmenopausal women from a general population. Sufficient numbers of serum specimens can be examined to allow reasonably firm conclusions about normal levels in this cancer-prone age group and to relate these levels to a variety of personal characteristics. Finally, it is proposed to ascertain if there are long-term changes in a variety of serum hormone levels with storage at minus 70 degrees C. This information is not currently available and is badly needed not only for this study but also for other investigations that rely on frozen serum specimens.

EPIDEMIOLOGY OF APLASTIC ANEMIA IN BALTIMORE

M. Szklo, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 CA 24757-02)

The overall objectives of this study are to examine the time trends and the environmental and host influences in aplastic anemia. In view of the association between aplastic anemia (AA) and acute myeloid leukemia (AML), an additional objective of the study is to compare the epidemiologic characteristics of these two disorders.

In order to accomplish these objectives, the study will be divided in two phases. In Phase I, all new cases of AA and AML occurring in metropolitan Baltimore will be identified from 1960 through 1979, and incidence and death rates will be calculated. In this phase of this study, the temporal trends of AA will be generated.

In Phase II, a case-control study will be conducted in which all new cases of AA occurring in metropolitan Baltimore from March 1980 through August 1982 will be compared with three groups: AML cases, and

both hospital and non-hospital controls. In this phase, specific hypotheses related to the etiology of AA will be examined, including past history of chemical exposure and viral diseases.

This investigation will attempt to define groups in the population who may be at a higher risk for AA, and possibly, also for AML. In addition, results may provide new leads in regard to the pathogenesis and natural history of AA, by assessing whether the occasional occurrence of AML among AA cases denotes a common epidemiologic pattern for these disorders.

RELATIONSHIP BETWEEN CHOLECYSTECTOMY AND ASCENDING COLON

L.H. Kuller, University of Pittsburgh, Graduate School of Public Health, Dept. of Epidemiology, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (R01 CA 24739-02)

A previous study of the epidemiology of subsite colon cancer in the Pittsburgh SMSA was based on the Third National Cancer Survey. Individuals with carcinoma of the ascending colon were noted to have a higher prevalence of prior cholecystectomy than individuals with carcinoma of the other sites within the colon. The information was only obtained by review of hospital records. We propose to determine the relationship between cholecystectomy and right sided colon cancer by doing a case control study. Cases of right sided colon cancer and controls consisting of carcinoma of the sigmoid and descending colon will be identified by reviewing hospital records and interviews. A living neighborhood control will also be interviewed.

MUTAGENIC AND CARCINOGENIC POTENTIAL OF ESTROGENS

R.H. Purdy, Southwest Foundation for Research & Education, *8848 W. Commerce St., Box 28147, San Antonio, Texas* 78284 (R01 CA 24629-01)

Epidemiological studies on the association of estrogen treatment and cancer in postmenopausal women indicate a clear need for basic investigations of the carcinogenic potential of different types of estrogenic hormones. It is our working hypothesis that a cancer risk is associated with the metabolically activated intermediates of some types of estrogens, and that the mutagenic potential of these estrogens will correlate with their rate of metabolic activation. This hypothesis will be tested using two established mammalian cell culture systems in order to determine the mutagenic and carcinogenic potential of several important types of natural and synthetic estrogens. Their relative effects on single-strand breakage of DNA and mutagenesis at the thymidine kinase locus will be measured in the L5178Y mouse lymphoma cell line. The effects of the metabolic activation products of these estrogens will also be examined in Balb/c3T3 mouse fibroblast cells to determine induction of DNA repair replication, and chemical transformation in this carcinogen-transformable cell line. If our hypothesis is supported by results from one or more of these cellular assays, it will provide a major insight into the mechanism of mutagenesis or carcinogenesis associated with estrogens.

CONFERENCE ON HEALTH EFFECTS OF ASBESTOS EXPOSURE

I.J. Selikoff, New York Academy of Sciences, Dept. of Environmental Medicine, *2 E. 63rd St., New York, New York* 10021 (R13 CA 24516-01)

Three coordinated scientific conferences, collectively entitled, 'The Scientific Basis for the Public Health Control of Environmental Hazards' will be held from 6/21-30/78. The individual conferences are 'Health Effects of Asbestos Exposure', 'Health Effects of Halogenated Aromatic Hydrocarbons', and 'Public Health Control of Environmental Hazards'. This format will provide an opportunity to examine and discuss a complex problem: Scientists are able, with increasing sophistication, to evaluate the hazards to health associated with, for example, the mining and quarrying of asbestos and asbestos-containing materials, the processing and fabrication of industrial and consumer materials containing asbestos and the eventual disposal of such materials. But, at the same time, they share with society-at-large an inadequate understanding of how to make the regulatory decisions that would effectively deal with the risks and benefits that accompany the use of materials that both fulfill a social need and, at the same time, pose a real threat to the health of the worker at the site of production as well as to the customer at large.

The societal control of environmental hazards is the central theme of this coordinated series of conferences. The Conference on 'Health Effects of Asbestos Exposure' will examine new material in this area and will emphasize the identification and evaluation of asbestos hazards, with a view to their more successful and systematic control. At the same time the asbestos conference will dovetail with the conference entitled 'The Public Health Control of Environmental Hazards' by serving as a prototypical example of the problems confronting our scientists and citizens at large when they attempt to deal with the control of environmental hazards.

ENDOMETRIAL CANCER EPIDEMIOLOGY AND CONTROL

P. Greenwald, State Bureau of Cancer Control, *Empire State Plaza, Tower Bldg. Rm. 565, Albany, New York* 12237 (R01 CA 24367-02)

This epidemiologic study of endometrial cancer monitors the incidence, severity, and mortality trends in a sample of cases reported to the New York State Cancer Registry during the years 1971 through 1981. Cases will be validated through histologic re-examination and re-staging of this sample. This will indicate if incidence is increasing for both advanced and early stages of the disease, and what effect this may have on future mortality rates.

The epidemiologic case-control component of the research focuses on the association between endometrial cancer and the use of estrogens. Specifically, we wish to determine if estrogen use is associated with advanced stage disease, and if there is a risk decline following termination of use. Additionally, we will ascertain through multivariate methods the factors which discriminate low grade and/or early stage cases from high grade, advanced stage cases. One hundred and fifty advanced stage and 200 early stage newly diagnosed endometrial cancer patients will be interviewed. A case to control ratio of 1:2 for advanced stage cases and 1:1 for early stage cases will be used.

FARMING AS AN OCCUPATIONAL RISK FOR CANCER

L.F. Burmeister, University of Iowa, School of Medicine, Dept. of Preventive Medicine & Environmental Health, *Jessup Hall, Iowa City, Iowa* 52240 (R01 CA 24302-02)

Recent work by others and preliminary data from this department have suggested that farmers are at greater risk for certain types of cancer than had been generally recognized. Using the Iowa agricultural population as a base, further exploration will include an improvement in rate and quality of occupational recording. This will be done by linkage with drivers' license tapes, direct mail questionnaires, recently completed independent studies and completion of death certificate coding. Both proportionate and standardized incidence and mortality rates will then be caluculated for all cancers by main occupational groups.

PSYCHOSOCIAL FACTORS IN STUDENTS PREDICTIVE OF CANCER

R.S. Paffenbarger, Stanford University, School of Medicine, Dept. of Family Community & Preventive Medicine, *Stanford, California* 94305 (R01 CA 24255-02S1)

This epidemiologic study will utilize observations on approximately 51,500 former students from Harvard and the University of Pennsylvania to identify psychosocial and other characteristics in youth predictive of site-specific and total cancers later in life. Physical examination and other college records of the years 1916-1950 comprise the initial data to be examined for associations with fatal and nonfatal cancers identified on death certificates or on self-assessed mail questionnaires during a 25-60 year followup period. To date, approximately 1,350 cancer deaths have occurred among these former students in approximately 1.85 million person-years of observation. The number of surviving (nonfatal) cancer patients has yet to be assessed. The study affords prospective perspective for both hypothesis testing and hypothesis seeking. Analytic methods will include case-control univariate methods applied to the total population, and exposed-nonexposed multivariate methods applied to the entire University of Pennsylvania and portions of the Harvard population.

Characteristics to be examined for their association with cancer represent psychological, social, demographic, physical, familial, and occupational factors. Site-specific cancers to be studied include lung, colorectal, pancreas, stomach, prostate, blood, lymphaden, and skin among men; and breast (and perhaps ovary, cervix, and endometrium) among women.

Unlike cross-sectional and retrospective studies that would search for associations between psychosocial characteristics and cancer occurrence, the proposed study will utilize predocumented data on adolescents and young adults and thus avoid the need to infer previous from current behavior or to recall mood, thought, or behavioral characteristics antecedent to cancer diagnosis.

CARCINOGENS AND MUTAGENS IN COLON CANCER

J.H. Weisburger, American Health Foundation Inc., *320 E. 43rd St., New York, New York* 10017 (R26 CA 24217-02)

The objective of our work is to obtain information on the nature of the chemical carcinogens which may be ingested as part of the diet. Various epidemiologic studies have suggested that dietary factors, particularly high dietary fat and beef, are of major importance in the etiology of cancer of the colon. A two-stage model has been suggested wherein the combined action of carcinogens and promoters are necessary for the development of large bowel cancer. The ability of high dietary fat to induce increased excretion of bile acids has been shown to be related to the promotion of tumors in the colon. The initiating agent remains unknown, but epidemiologic evidence has implicated broiled meat.

Several groups have reported mutagenic activity in meat cooked either by charcoal broiling or by frying. Nagao et al. noted that the mutagen is formed during pyrolysis of protein. Commoner et al. suggested that a critical temperature of 150-200 degrees C must be passed before the mutagen forms. Since this temperature range is not reached in broiling, he concludes that this mode of cooking is 'safe.' We propose to demonstrate that all modes of cooking have the potential to produce mutagenic material and are isolating the mutagens in order to assay their carcinogenicity.

AN EPIDEMIOLOGIC STUDY OF CANCER OF THE OVARY

G.B. Hutchison, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115 (R01 CA 24209-01S1)

A case-control study of ovarian cancer is involving 400 patients with this disease and 400 controls selected from the general population. The pathology for each case will be reviewed and classified according to specific histologic type by a recognized expert in ovarian cancer pathology. Personal, home interviews will be conducted to assess a variety of epidemiologic factors including general medical and family history, occupation, tobacco and alcohol habits, pregnancies, breast feeding, contraceptive experi-

ence, and drug use, including intrauterine exposure to drugs for the younger subjects. We will estimate the total number of ovulatory cycles as well as the longest series of consecutive ovulatory cycles uninterrupted by pregnancy, lactation, or oral contraceptive use and determine whether these measures correlate with ovarian cancer risk. Also of major interest are the relative risks associated with the use of oral contraceptives and hormones for the menopause. A doubling risk of cancer associated with several of the risk factors under study will be detectable in subgroups of ovarian cancer of size 75 or more. Our goal is to identify risk factors that may be modified to reduce disease occurrence primarily or that may be of clinical usefulness in defining the woman at risk of ovarian cancer to achieve better control of the course of the disease secondarily.

ENVIRONMENTAL EXPOSURES AND CHILDHOOD LEUKEMIA

T.W. Pendergrass, Childrens Orthopedic Hospital & Medical Center, Hematology & Oncology Division, *4800 Sand Point Way N.E., Seattle, Washington* 98105 (R23 CA 24186-02)

Little is known of the role of parental occupational exposures or perinatal drug ingestion in the subsequent development of childhood acute lymphocytic leukemia. This study has two goals: a) development of a method for obtaining parental occupational and perinatal drug exposures, and b) testing this method on parents of children diagnosed as having acute lymphocytic leukemia, between 1972 and 1979 in the State of Washington. Cases have been identified in the three major hospitals treating children with cancer in the State. For each case a hospital control has been selected to attempt to control for any differences in recall between parents of ill and presumably well children. General population controls will be obtained by use of a random digit dialing method. To date, 80% of case parents have been interviewed. Occupational data include a detailed review of occupational history and review of each job-related exposure. A detailed review of perinatal drug ingestion is obtained.

2.0615,

RELATION OF CANCER RATES AND SOURCE OF DRINKING WATER

I. Cech, University of Texas, Health Science Center at Houston, School of Public Health, Dept. of Environmental Sciences, *6515 Freeman, Houston, Texas* 77025 (R01 CA 24138-02)

One of the most controversial issues of concern to public health and water resources personnel is the relation between drinking water and cancer. This problem was highlighted when Robert Harris of the Environmental Defense Fund reported that higher rates of total cancer, cancer of the urinary system and of the gastrointestinal tract were observed among individuals drinking treated surface water from the Mississippi River in Louisiana, New Orleans area, compared to others, drinking ground water in the same state. Significant, however, has been the rapid shift from the basic issue, i.e., is the difference observed in cancer rates among the users of different water supplies limited to Louisiana or is it initial evidence of a more general phenomena? Apparently the Louisiana observation has been accepted as a causal association, since focus has shifted to a search for the particular water contaminant(s) responsible for the observed differences, specifically, to the health risk from waterborne chloro-organic compounds, some of which were shown to be a product of chlorine-disinfection process.

Although evaluation of the health risk of water chlorination has merit, the narrowing of the entire research focus on the matter of chlorination has been hasty. If the observations in Louisiana hold true in other areas, it increases the likelihood of the existence of a water related causal factor which may well be other than chlorination. The fact is, however, that the evidence of the link between cancer and source of drinking water is insufficient for acceptance. A promising and appropriate line of investigation would be to critically and thoroughly examine this basic issue by analyzing cancer mortality rates among the users of both categories of water supplies. The objective of this proposal is to examine cancer mortality and patterns of water utilization in Texas, and to assess the cancer risk in populations using surface and ground sources of drinking water within and among Texas' 254 counties, with geographic references to specific river basins and major ground water aquifers from which the supply is derived.

CASE-CONTROL STUDY OF URINARY CANCER, COPENHAGEN

J. Clemmesen, Finseninstitutet, Danish Cancer Registry, *Strandboulevarden 49, DK2100 Copenhagen, Denmark* (R26 CA 24119-02)

Rates for urinary bladder tumors are known to be relatively high for Copenhagen, and have proved to considerable extent associated with tobacco smoking. While rates for lung cancer are about half the English, rates for bladder tumors are almost equal in the two countries, although occupational bladder tumors are not known in Denmark, in contradistinction to England.

For these reasons a case control study for urinary tract tumors has been established in Copenhagen collaborating with nearly all urological surgical departments in the city.

Patients are, as usual, reported to the Cancer Registry which per Oct. 1st, 1979 has provided for interviews with 70 bladder patients and 55 population controls, and with 24 ureter and pelvis cancers with 40 hospital controls.

The study is in progress.

BREAST CANCER IN INITIALLY ASYMPTOMATIC WOMEN

B.S. Pasternack, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016

OBJECTIVES: To investigate by means of risk factor analysis whether minimal cancer in initially asymptomatic women is essentially different from clinical breast cancer, whether it is an early manifestation of the same disease, and to compare prevalent to incident breast cancer cases in order to identify risk factors associated with tumor aggressiveness. To achieve these goals, we will analyze data collected by the Guttman Breast Diagnostic Institute which since 1968 has been offering free breast examinations to women living in New York City. Cases will be compared according to three tumor criteria: level of invasiveness, level of aggressiveness, and histological type. If risk factors related to higher malignancy (invasiveness) and rapid growth (aggressiveness) are identified, then future screening efforts can be redirected towards detecting these biologically important breast cancers.

SCREENING TECHNIQUE FOR DETECTING EARLY CANCER OF BOWEL

V.A. Gilbertson, University of Minnesota, Minneapolis Campus, School of Medicine, Dept. of Surgery, *1305 Mayo, Minneapolis, Minnesota* 55455

During the coming year, the contractor will complete the first stage screening for all project participants, complete and analyze all dietary/health surveys (of over 45,000), analyze the periodic health status survey collected annually from all participants, with particular attention being given to current screening results, record and retest all interval cancer cases known to the project. There will also be presented the conclusions of the Death Review Committee of all cancer deaths omong the study participants with priority given to cases involving colon cancer. The coming contract year will allow a complete report, evaluation and analysis to be prepared concerning the complex follow-up protocols used for tracing and retention. This process refers to procedures required to trace and obtain responses from all living members of the project population.

MORPHOLOGIC AND EPIDEMIOLOGIC ASPECTS OF BREAST CANCER

B. Stenkvist, Uppsala Universitet, *Box 256, S75105 Uppsala, Sweden*

The Contractor intends to select randomly 100 out of about 1000 imprint specimens from different tumors. The specimens will be interactively analyzed in their cell analysis system, and the result from this processing will be saved and later subjected to careful statistical analysis on a large-scale computer, in order to define a measure characterizing nuclear grade for each one of the selected tumors. He also intends to see if there are any natural categorizations of the tumors from the nuclear-grade point of view. The results from these experiments will be compared with the conventional classification used by pathologists and cytologists. In order to evaluate the importance of the obtained measure of nuclear grading, he intends to relate it to the three- and five-year survival of the patients in a follow-up study.

2.0621,

CLEARINGHOUSE FOR ONGOING WORK IN CANCER EPIDEMIOLOGY

C.S. Muir, Centre International de Recherche sur le Cancer, *150 Cours Albert Thomas, 69372 Lyon Cedex 2, France*

Establishment of a clearinghouse for ongoing work in cancer epidemiology.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. funds n.a.

2.0622,

AN EPIDEMIOLOGICAL INVESTIGATION OF CANCER IN UTAH

J.L. Lyon, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Surgery, *1400 E. 2nd S., Salt Lake City, Utah* 84112

Patient follow-up after diagnosis and treatment has been a major objective of the registry since its beginning in 1966. Information is collected from hosptials, physicians, pathology laboratories, radiotherapy centers and the Utah State Division of Health and is processed quarterly by computer. If a patient has not been seen by a physician within one year, the computer will generate a follow-up letter to be sent to the responsible physician. The registry has accessioned over 33,000 cases, approximately half of which are alive and being followed. About 2,000 cases are registered each year from Utah and another 2,000 from the neighboring states of Nevada, Idaho, Montana, and Wyoming. Other states are processed separately and the registry is paid $1.50 per case for this service. Reporting is not complete in these states so no incidence data are available.

2.0623,

EPIDEMIOLOGY AND GEOGRAPHIC PATHOLOGY OF CANCER

P. Correa, Louisiana State University, Medical Center, School of Medicine, Dept. of Pathology, *1542 Tulane Ave., New Orleans, Louisiana* 70112

Continue collaborative research with investigators in Latin America. Continue pathological studies of premalignant lesions in New Orleans autopsy and surgical pathology specimens, and to correlate findings with incidence and pathology data from other communities. These studies will focus on premalignant lesions in the large bowel, esophagus, and pancreas. Continue laboratory studies aimed at finding ways to elaborate and test hypotheses derived from studies of epidemiology and geographic pathology. This will include a comparative study of the mutagenic activity in fecal specimens from polyp-bearers and controls.

2.0626,

SUPPORT FOR CANCER EPIDEMIOLOGY PROGRAM

J.W. Meigs, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510

Identify correlates of cancer in Connecticut by defining patterns in the occurrence of cancer among groups and populations by age, sex, ethnicity, occupation, residence, medical history and prior therapeutic experience, and other variables, particularly socioeconomic. This will require both retrospective and prospective studies involving patients as well as records.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $122,455

2.0627,

GEOGRAPHICAL PATHOLOGY AND EPIDEMIOLOGY OF CANCER

C. Cuello, Fundacion para la Educacion Superior, *Cali, Colombia*

The objectives of this study are to determine site-specific cancer incidence in Cali and other cities in Colombia, to correlate the local variation in morbidity data with pathology findings, and for selected sites such as thyroid, stomach, colon, and rectum to fit the Colombian findings into the epidemiological patterns observed in the United Statesand elsewhere in an effort to achieve a broader synthesis of epidemiology and etiology. The proposal is for three yearsof work which will include three major efforts, namely, an epidemiologic study of the factors related to stomach cancer in the high risk Department of Narino, a cancer registration and record linkage program in conjunction with the social security system, and collaboration with investigators in Brazil, Venezuela, and Costa Rica, on the epidemiology and pathology of cancers of the gastrointestinal tract. In addition, current investigations in Colombia will continue on cancers of the colon, prostrate, thyroid, cervic, and lymphomas.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $50,692

2.0628,

SUPPORT FOR LOUISIANA TUMOR REGISTRY

E.T. Krementz, Charity Hospital of Louisiana, *1532 Tulane Ave., New Orleans, Louisiana* 70140

OBJECTIVES: Provide data for incidence and end results reporting on all cancers diagnosed among residents of the Metro New Orleans area. The reporting system will be implemented for Orleans Parish while negotiations to increase participation in Jefferson and St. Bernard Parishes continue. Data from all SEER participants are pooled and analyzed by NCI staff to determine changes over time in the use of different methods of therapy and of diagnostic criteria, and to determine the survival patterns associated with various treatment modalities. The contractor is required to submit supplementary data for studies designed to explain further any specific hypotheses suggested by analysis of the routinely submitted data.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $489,449

2.0629,

STUDY OF HODGKIN'S DISEASE

N. Goldblum, Hebrew University of Jerusalem, Hadassah Medical School, Dept. of Virology, *P.O. Box 1172, Jerusalem 91000, Israel*

OBJECTIVE: To investigate, evaluate and identify the relative roles played by various environmental and hereditary factors in the etiology and epidemiology of Hodgkin's disease and other types of lymphoma with an emphasis on the types which are indigenous to the Middle East.

APPROACH: An epidemiologic study of incidence of histologic subtypes, the determination of survival of cases of Hodgkin's disease in relation to ethnic groups, and evaluation of clustering of Hodgkin's disease in space and time, and among social contacts. A variety of assays, such as HLA typing, EBV serology, concanavalin A tests of lymphocytes and other assays, are applied for evaluating susceptibility to various types of lymphoma. A detailed study on childhood lymphoma is performed in order to identify immunoepidemiologic and laboratory parameters relating to Burkitt's lymphoma in Israel, Africa and the United States. Specially selected cell lines isolated from these lymphomas are characterized for markers specific to the lymphomas found in the Mediterranean region; these include cell surface characteristics, immunoglobulin, cytologic and karyotypic markers.

PROGRESS: Included in yearly and half-yearly progress reports to the N.C.I. A new type of malignant lymphocyte was established in continuous culture which is the malignant cell of non-African, non-EBV genome carrying Burkitt's tumor. A diagnostic differential test for lymphoma has been developed using fluorescent concanavalin A.

ESTROGENS AND GENITAL ANOMALIES AND CANCER IN OFFSPRING

R.H. Kaufman, Baylor College of Medicine, School of Medicine, Dept. of Obstetrics & Gynecology, *1200 Moursund Ave., Houston, Texas* 77025

OBJECTIVE: Identify and study offspring of women who received synthetic estrogens during pregnancy between 1943 and 1963. Repeat examinations at regular intervals, perform diagnosis and follow-up and treatment as necessary. Approximately 1,000 offspring are to be examined on this contract.

PROPOSED COURSE: The contractor will establish standard definition of eligibles and develop suitable approaches to elicit eligibles through information campaigns to physicians and the general public via mass media. Evaluation will be performed and reported.

PROGRESS: A total of 548 participants have been entered as of March 1976. Of these, 519 are active participants with 446 having documentation of DES exposure in utero. Chart reviewing by physicians in the Houston area has been the primary source of participants. Also, the health services at local universities have been used as an outreach to women students. Consent forms have been utilized.

JAPAN-HAWAII CANCER STUDY

A.M. Nomura, Kuakini Medical Center, *347 N. Kuakini St., Honolulu, Hawaii* 96817

The objective has been to use the Japanese migrating to Hawaii for epidemiological studies of host characteristics and environmental factors in site-specific cancers with special attention to stomach, large bowel, prostate and breast. To elaborate leads obtained through case-control studies a cohort of about 10,000 Hawaiian Japanese (originally assembled by NHLI for studies of cardiovascular disease) has been examined and remains under active surveillance for morbidity and mortality experience. Surveillance includes autopsies of cohort members (35-40 percent of all deaths).

2.0637,

EPIDEMIOLOGY OF PRE- AND POST-MENOPAUSAL BREAST CANCER

R.S. Paffenbarger, University of California, Berkeley Campus, School of Public Health, Dept. of Biomedical & Environmental Health Sciences, *Berkeley, California* 94720

Study retrospectively (by case-control) at least 500 pre-menopausal and at least 1000 post-menopausal cases, together with appropriate controls, defining epidemiologic characteristics with precision for all groups. Conduct the study across socio-cultural groups with difficult risk levels, using established methods of obtaining standard epidemiologic information. Special emphasis can be placed on exogenous estrogen intake and on behavioral information, at the investigator's discretion. Analyze the data by recognized and defined biostatistical methods, classifying pre-, perip-, and post-menopausal women as separate groups.

2.0638,

EPIDEMIOLOGY OF MEDULLARY AND LOBULAR BREAST CANCER

P.P. Rosen, Memorial Sloan Kettering Cancer Center, *1275 York Ave., New York, New York* 10021

The primary objective is to compare risk factors for the less common histologic types of breast cancer, such as lobular and medullary cancers with the more common infiltrating ductal types which comprise approximately 80% of breast cancers in the United States. Preliminary epidemiologic data is suggesting that the less common types of breast cancer may have some epidemiologic characteristics of their own. Although lobular and medullary breast cancers are relatively rate, it is conceivable they may fit into epidemiologically definable patterns.

2.0639,

EPIDEMIOLOGY OF PRE- AND POST-MENOPAUSAL BREAST CANCER

D.C. Deubner, Duke University, School of Medicine, Dept. of Community & Family Medicine, *Box 3711, Durham, North Carolina* 27710

This study consists of 00 breast cancer patients undergoing surgery at hospitals, 800 age-race matched surgical, medical or family practice patients not having breast or gynecological surgery at the same hospitals, and 1800 subjects from the community. Data collection is by interviews and review of hospital charts. Laboratory studies on tissue and serum from patients will include quantitative estrogen and progesterone receptor determinations, evaluation of histology and ultrastructure by a standardized protocol, and estrogen and progesterone serum determinations. Statistical analyses will estimate the relative strength of association between breast cancer in pre- and post-menopausal women and such factors as age of menarche, first delivery, obesity, and family history of breast cancer. Associations between risk factors and tumor cell biology and morphology will be sought by comparing the laboratory results in women with and without single or multiple risk factors.

2.0651,

A PROSPECTIVE COHORT FOR RISKS IN BREAST CANCER

F.E. Speizer, Harvard University, Boston Campus, Peter Bent Brigham Hospital, *721 Huntington Ave., Boston, Massachusetts* 02115 (R01 CA 23645-03)

This investigation is designed to follow prospectively a cohort of approximately 120,000 women, ages 30-54, in whom exposure to oral contraceptives, estrogens, cigarette smoking, and hair dyes has been documented. Morbidity and mortality for a variety of cancers, including breast, endometrial, ovary, lung, and other cancers, as well as cardiovascular events, benign breast disease, and other benign obstetric and gynecologic events such as infertility and outcome of pregnancies will be followed. The approach is by mail questionnaire with further documentation of events by review of hospital records and pathologic specimens.

The cohort was defined from the register of Registered Nurses collected by the American Nurses Association in 1972 and recorded at that time as being married women. Those women who on January 1, 1976, were between the ages of 30-55 and who responded to an inquiry in 1976 which collected - besides data mentioned above - information on menstrual history, height, weight, current contraceptive status and family history of myocardial infarction and breast cancer in female relatives constitute the cohort. In adddition, an estimate of social class status at age 16, based on parental occupations, was obtained. second questionnaire was mailed in June 1978. Over 100,000 responses have been received, and these data are being assessed for developments.

EXPLORATORY STUDIES IN CANCER PATIENT DATA CONTROL

R.M. Elashoff, University of California, Los Angeles Campus, School of Medicine, Dept. of Biomathematics, *2025 Zonal Ave., Los Angeles, California* 90024 (R10 CA 23636-02)

During the first eight months of the initial grant year, we have transmitted to SAQC complete data on the Minimal Dataset and have almost completed planning on modifications on our current computer system to transmit data in the efficient way of data tapes to SAQC. Also, we have reviewed and suggested protocol changes for CCPDS planned clinical studies and have explored use of CCPDS in health services mode.

Our largest time commitments had to be spent on changes to our present computer system. These changes are based in off-the-shelf software modules in which some UCLA written programs will be developed. The entire system will be reliable, portable and minimally idiosyncratic to UCLA. The next grant period will see a near-operational computer system in place.

An additional major effort during the next grant year is to try to get clinical and/or epidemiological and/or health services research proposals using CCPDS completed.

2.0653,

IMMUNOPATHOLOGY OF X-LINKED LYMPHOPROLIFERATIVE SYNDROME

D.T. Purtilo, University of Massachusetts, Medical School at Worcester, School of Medicine, Dept. of Pathology, *419 Belmont St., Worcester, Massachusetts* 01604 (R01 CA 23561-02)

Our objective is to study the immunopathology of the X-linked recessive lymphoproliferative syndrome (XLP) which is expressed phenotypically as diverse lymphoproliferative disorders: acquired agammaglobulinemia, fatal infectious mononucleosis, or malignant lymphoma. Three comprehensive approaches are proposed: (1) Develop a registry to ascertain the prevalence, delineate phenotypic expressions, and develop diagnostic criteria. Cases will be ascertained by referrals and review of medical literature and cases in tumor registries and in pediatric and general hospitals. (2) Patients with the XLP will be evaluated for general immunocompetence using clinical, hematopathological and immunological and virological techniques. Blood, bone marrow, biopsy and autopsy specimens will be studied intensively using the above techniques. Males with XLP are probably immunodeficient to Epstein-Barr virus (EBV) and hence, we will test our hypothesis by demonstrating: a) spontaneous outgrowth of EBV-infected B cells in vitro; b) EBV shedding in saliva; c) failure to develop antibody to EBV; and d) abnormal autologous T cell responses to B cells infected by EBV in vitro. Testing is important diagnostically and could identify the immunopathogenetic mechanisms of the XLP. (3) Genetic screening for affected males with XLP and female carriers is being done by studying the Xga blood group and oculocutaneous markers, measuring general and EBV-specific immunocompetence, and detecting abnormal lymphocytes with heteroantisera raised to lymphocytes of patients and HLA-matched female siblings. Karyotyping of lymphoblastoid cell lines of patients will determine whether chromosomal breakage and marker chromosomes occur following infection by EBV in males with XLP. The development of a repository of their frozen sera, saliva and cultured lymphoblastoid cells for future studies is another objective of our study.

2.0654,

CASE-CONTROL STUDY OF MALIGNANT MELANOMA

A.K. Bahn, University of Pennsylvania, School of Medicine, Dept. of Research Medicine, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (R01 CA 23544-01A1)

This is a two-year case-control study of 225 cases and matched controls resident in Northern New Jersey. All white males between the ages of 30 and 64 years in the selected counties with a diagnosis of malignant melanoma who were first diagnosed between July 1, 1978, and December 30, 1980, will be eligible as cases. Age-sex-race population matched controls will be selected.

Information obtained from records of private dermatopathology laboratories and hospital pathologist records will be used to determine cases aided by the New Jersey, New York and Pennsylvania cancer registers. All cases will be ascertained as malignant melanoma by a board certified dermatopathologist. Home interviewing of cases and controls will obtain information on: residence history, work exposure history (particularly to chemical substances), sun exposure, history of cancer in the family and history of chloracne dermatitis.

Preliminary work has provided suggestive evidence of a large relative risk of malignant melanoma among workers exposed to polychlorinated biphenyls (PCBs) and other chemicals. New Jersey has been selected as the locale for the study because this state has the largest number of workers in chemical and related industries in the nation and because high melanoma mortality rates (for an area outside the South) have been noted among males.

Investigation will be carried out to determine if there are significant differences between cases and controls in exposure to chemical substances, exposure to sunlight, or a previous history of chloracne dermatitis.

CERTIFICATION OF CANCER RELATED DEATHS

G.C. Myers, Duke University, Center for Demographic Studies, Dept. of Sociology, *Durham, North Carolina* 27706 (R01 CA 23399-02)

An evaluation of the accuracy of death certificate diagnosis of cancer for the state of North Carolina during 1975-1977 is conducted by matching such diagnosis with information gathered from hospital records. A major purpose of the study is to determine not simply whether cancer was present or absent at death, but to investigate the nature of the contribution of cancer to death, especially vis a vis other associated chronic illnesses (e.g., diabetes, heart disease, and stroke). Also the significant clinical events in the natural history of cancer caused deaths will be studied. The intent is to determine the completeness of death certificate diagnosis of major complications of the cancer underlying cause of death. In addition an analysis will be made of the appropriateness of the selection of cancer as the single underlying cause of death in the NCHS produced national mortality data. Analyses will examine the variation of the diagnostic accuracy and clinical significance of deaths reported as caused by cancer in national vital statistics data across a number of variables of interest (e.g., sex, race, age, cancer type, assocated chronic conditions, institution types and residence).

EPIDEMIOLOGY OF MYELOMA AND LYMPHOCYTIC LEUKEMIA

N.S. Weiss, Fred Hutchinson Cancer Research Center, *1124 Columbia St., Seattle, Washington* 98104 (R01 CA 23350-01S1)

We propose a collaborative case-control study to identify and evaluate risk factors for multiple myeloma and chronic lymphocytic leukemia. Cases of these diseases will be identified through population-based cancer registries in Washington State, Utah, Detroit and Atlanta, over a three-year period. Control subjects will be identified from the general populations from which the cancer cases arose. Probability sampling methods, such as area sampling and random digit dialing, will be used for selection of controls. Cases and controls will be interviewed with particular attention to variables related to chronic antigenic stimulation, e.g., past illnesses, allergies, drugs, etc. We will also obtain detailed residence and occupational information in an attempt to generate new etiologic hypotheses.

CANCER CONTROL OUTREACH PROGRAM AT FOX CHASE

M.H. Donaldson, Inst. for Cancer Research, *7701 Burholme Ave., Philadelphia, Pennsylvania* 19111 (R18 CA 23321-02)

The objective of this program is to expand the current cancer control activities of The Fox Chase Cancer Center. A primary goal is to develop new outreach projects, interacting with segments of the medical community and the public in ways which are designed to ultimately benefit overall care and rehabilitation of the cancer patient. Demonstrations programs as well as continuing education for health professionals and cancer-related health education for the general public will be transmitted by multidisciplinary teams operating through a network of affiliated community hospitals, primary health care centers and private physicians. The program design permits an individualized approach to each element of the network, based on needs and resources of the faculty and the community.

LUNG CANCER AND VITAMIN A

A. Lopez, Louisiana State University, Medical Center, School of Medicine, Dept. of Medicine, *1542 Tulane Ave., New Orleans, Louisiana* 70112 (R01 CA 23205-02)

The objective of this research project is to ascertain the relationship between vitamin A and lung cancer. This study is being carried out in Louisiana, a state known to have very high incidence of lung cancer. Preliminary analysis of available data (National Nutrition Survey and HANES) indicates a negative correlation between beta-carotene (precursor of vitamin A) and mortality rates due to respiratory system cancers and also with mortality from all neoplasms, but not with total deaths. We have also initiated case control studies in which dietary intakes and vitamin A concentration in hepatic tissue of patients who died of lung cancer will be compared with those in appropriate controls. Studies have also been started in living patients suffering from lung cancer. Serum level concentrations and dietary intakes of vitamin A are measured and compared with those from matched controls. The information to be obtained from these studies would provide evidence for the suggested relationship between vitamin A (and/or other nutritional factors) and lung cancer.

STUDIES OF CHILDHOOD SOLID TUMORS

J.V. Simone, St. Jude Childrens Research Hospital, *332 N. Lauderdale St., P.O. Box 318, Memphis, Tennessee* 38101 (P01 CA 23099-02)

Cancer is the leading cause of death from disease in children past one year of age in this country. Significant improvement has resulted from treatment regimens designed for the most common form of childhood malignancy, acute lymphoblastic leukemia. While progress in cases of some of these solid tumors of children has been notable, such as in Wilms' tumor and Hodgkin's disease, the effectiveness of treatment regimens for most childhood tumors has been disappointing. In large part, the difficulties of disease control result from the fact that for many childhood tumors the disease has already disseminated beyond the site of origin at the time of diagnosis. Therefore, for most children with solid tumors a coordinated approach involving surgery, radiotherapy, and chemotherapy is necessary.

The role of chemotherapy is extremely important. To this end, this project will develop studies for neuroblastoma, osteosarcoma, and large bowel cancer, to investigate methods of improved therapy. Clinical and laboratory research will be brought to bear on these disease areas. In addition to these specific disease categories, there will be three general areas of research involving all patients with these tumors. These studies will include Phase I and II drug testing programs, altered drug pharmacokinetics, and epidemiology.

SECOND CANCERS IN PATIENTS WITH HODGKIN'S DISEASE

G.B. Hutchison, Harvard University, Boston Campus, School of Public Health, Dept. of Epidemiology, *55 Shattuck St., Boston, Massachusetts* 02115 (R01 CA 22849-03)

OBJECTIVES: To determine the long-range hazard, in terms of carcinogenesis, of radiotherapy and of chemotherapy used in treatment of Hodgkin's disease.

SPECIFIC AIMS: (1) To determine the incidence of second primary malignancies in patients treated with modern modalities for primary Hodgkin's disease. (2) To determine the variation in incidence of second primary malignancies by modality of therapy for primary Hodgkin's disease, comparing: (a) non-intensive radiotherapy; (b) intensive radiotherapy; (c) non-intensive chemotherapy; (d) intensive chemotherapy. (3) To determine the variation in incidence of second primary malignancies by time since initiation of therapy for Hodgkin's disease. (4) To determine the distribution by organ site of second primary malignancies.

METHODS: A cohort study is being conducted, using retrospective data on Hodgkin's disease patients diagnosed in 1940 to 1975 and followed to 1976 or death before 1976 and using prospective data on these same patients followed to 1980 and on patients newly diagnosed after 1975 and followed to 1980. It is planned to enroll 1000 patients diagnosed in 1940-69 and 1000 patients diagnosed in 1970-78. Patients with Hodgkin's disease are ascertained through registration records of four large cancer treatment centers.

CANCER AMONG HOUSEHOLD CONTACTS OF ASBESTOS WORKERS

H.A. Anderson, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (R01 CA 22792-02)

Cancer risk associated with exposure to asbestos is well established. The greatest risk is that suffered by workers; however, environmental exposure in the households of workers may also result in disease. While mesothelioma has been found among household contacts, quantitation of this risk has not been undertaken, nor is it known whether other asbestos-associated diseases (lung cancer, GI cancer) are also increased.

In another study, we have established the mortality experience of cohort of asbestos factory workers. In this investigation, we will study the mortality experience (1946-1980) of the family contacts of these asbestos factory workers, who resided in their households during the period of factory employment (1941-45). Some data are available concerning the levels of their exposure. In a preliminary study, we determined that the family cohort can be identified and traced, and that cause of death can be determined for those who have died.

In the first year of study, most household contacts of the index workers were identified and a determination of their vital status initiated. Utilizing records maintained as part of study of index workers and various tracing techniques, it has been possible for the field to identify all household contacts of 856 of 933 workers (92%). Of the 856 workers, 122 (14%) lived alone. For the remaining 734, 2,175 household contacts have been identified. 1,617 are reported to be alive and 558 are deceased. Death certificates have been obtained on 518 (93%) to date.

BIOMATHEMATICAL APPROACHES TO CANCER

A.G. Knudson, Inst. for Cancer Research, *7701 Burholme Ave., Philadelphia, Pennsylvania* 19111 (R01 CA 22780-02)

This is a multi-investigator project that applies mathematical and statistical methods to the etiology of cancer and to the elucidation of biological mechanisms relevant to cancer biology. (1) International data on the incidences of various human cancers are being compared with mathematical models that allow for growth of stem cells and the occurrence of two or more critical cancer mutations. (2) Selected international populations are being investigated for the development of hepatic cancer following infection with hepatitis B virus. Immune responses are monitored and the roles of congenital viral infection, nutritional status, and serum iron level evaluated. (3) Linear discriminant analysis is applied to data on the age-specific incidences of cancers of various kinds in rats as a function of early nutritional history. (4) Mathematical models are being developed that describe the population behavior of F' and F negative bacteria under conditions in which the plasmid can be acquired or lost. (5) The interactions of carcinogens with nucleic acids and of enzymes with substrates and metals are being studied by X-ray crystallography and NMR spectroscopy. Theoretical molecular models are built and 3-dimensional representations displayed graphically. (6) A mathematical analysis is being developed to permit the calculation of the number of molecules of a particular RNA species at a given time following viral infection. (7) Other projects include models for the study of antibody diversity, the analysis of family clusters, the mechanism of bacteriophage attachment, and the application of the thermodynamic theory of fluctuations to epigenetic variation in cell biology.

A PROSPECTIVE STUDY OF PERSONALITY AND RISK OF CANCER

R.B. Shekelle, Rush University, School of Medicine, Dept. of Preventive Medicine, *1725 W. Harrison St., Chicago, Illinois* 60612 (R01 CA 22536-03)

The Western Electric Health Study began as a prospective epidemiologic investigation of coronary heart disease in 1958 with examination of 2,107 male employees aged 40-55 years. The Minnesota Multiphasic Personality Inventory (MMPI) was included in the 1958 examination, the Cattell 16 Personality Factor Questionnaire in the 1959 examination, a social factors questionnaire in 1960, and the MMPI again in 1962. Questionnaires from participants of next-of-kin and death certificates will be used in 1978-79 to identify possible incident cases of cancer; medical and hospital and records will be reviewed for information about diagnosis, treatment, and course of the disease. A total of 246 incident cases are expected. Two separate hypotheses will be investigated: (1) that psychological depression, as measured by the scale in the 1958 MMPI, is associated with increased 20-year risk of cancer, and (2) that characteristic use of denial and repression, as assessed by Welsh's Factor R in the 1958 MMPI, is similarly related to increased risk of cancer. In addition, item analysis and discriminant analysis will be used to search for other aspects of personality that may be related to cancer incidence. Factors such as age, smoking habits, consumption of alcohol, and educational attainment will be taken into account. Analyses will be conducted for all cases of cancer together and, where numbers are adequate, for site-secific categories. The results of this study will help to establish whether previous findings concerning the association of psychologicl factors cancer were artifacts of the retrospective method or whether these previous findings, in fact, represent premorbid psychological characteristics of persons who develop cancer.

EPIDEMIOLOGY OF BRAIN TUMORS

F.H. Hochberg, Massachusetts General Hospital, Neurology Service, *32 Fruit St., Boston, Massachusetts* 02114 (R01 CA 22533-02)

A case-control study of 230 patients and 230 'best friend or closest neighbor' controls is proposed to evaluate risk indicators of primary brain tumors (specifically histologically confirmed astrocytic tumors: astrocytoma, glioma, glioblastoma multiforme, medulloblastoma). Despite the fact that brain tumors are the primary source of cancer mortality in youth, that a variety of brain tumor risk factors have been suggested, and that experimental data exist linking brain tumor development to specific chemical carcinogens and oncogenic viruses, no large population-controlled study has been done to determine the risk factors of brain tumor. Through self-administered questionnaire and telephone interview, we propose to: 1. Determine the relationship between demographic characteristics and risk of glial tumors. 2. Evaluate the role of occupational and environmental exposures and risk. 3. Evaluate the role of trauma. 4. Evaluate the role of familial factors. 5. Evaluate the role of infection as a risk factor. Although this study is analytic in design, it is hypothesis-generating in nature. The unique availability of a patient population which includes 100 new astrocytoma patients per year and the active brain tumor research interests of the investigators have created a situation in which a valid study of the epidemiology of these tumors may be completed in an efficient and inexpensive manner.

BIOCHEMICAL STUDIES IN CHEMICAL CARCINOGENESIS

J.A. Miller, University of Wisconsin, Madison Campus, Medical School, Dept. of Oncology, *307 N. Charles St., Madison, Wisconsin* 53706 (P01 CA 22484-03)

The research supported by this program-project grant provides an integrated approach to the elucidation of the nature of the carcinogenic process. The studies in Drs. J.A. and E.C. Miller's group are primarily concerned with the early steps in the carcinogenic process, i.e., the nature of the ultimate carcinogenic derivatives, the identities of macromolecu-

lar adducts formed from them in vivo, and the consequences of the interactions of the carcinogens with DNA or other macromolecules. The research in Dr. Boutwell's laboratory seeks to elucidate the molecular nature of promotion, especially in mouse skin. Dr. H.C. Pitot and Dr. V.R. Potter are both analyzing aspects of the initiation and promotion of hepatic carcinogenesis. Both of these research groups are also analyzing aspects of the metabolic capacity of liver in cell culture as compared with that in the whole animal in relation to the controls introduced by various hormonal situations and other modifying agents. Dr. Poland's work has centered on the examination of the toxicity of 2, 3, 7, 8-tetracholor-p-dioxin, a compound of considerable interest in view of its high toxicity and the development of tumors in rats given very low doses.

BIBLIOGRAPHIC REFERENCES: Leopold, W. R., Miller, E. C., and Miller, J. A. Carcinogenicity of Anti-tumor cis-Platinum (11) Coordination Complexes in the Mouse and Rat. Cancer Res., 39: 913-918, 1979. MOLECULAR ANALYSIS OF MALIGNANT TRANSFORMATION

A.B. Pardee, Sidney Farber Cancer Center Inc., Laboratory of Tumor Biology, *44 Binney St., Boston, Massachusetts* 02115 (P01 CA 22427-03)

We propose to investigate a range of questions regarding the transformation of cells to malignancy, the role of mutagens and anti-mutagens in this process, and the distinguishing molecular events associated with neoplasia. Efforts of the individual investigators will interdigitate with respect to research plans, joint experiments, literature review, and sharing of facilities used for these studies. The specific problems to be investigated are the following: I. Maintenance of chromosome stability: structure and function of the telomere. II. Quantitative assays of mutagenic and carcinogenic susceptibility of human cells. III. Protection of cells against neoplastic transformation using agents that alter DNA repair processes. IV. Studies of transformation-sensitive cell surface proteins. V. The role of platelet wound hormone in transformation, cellular quiescence, and epithelial cell growth. The methodologies to be applied include tissue culture, cell implantation in athymic (nude) mice, recombinant DNA, biochemical methods for studies of DNA and protein, autoradiography and other radioactive tracer methods, and isolation and characterization of mutated and transformed cells.

A PILOT DEMONSTRATION DETECTION PROGRAM

V.F. Greco, Community Cancer Corp. of Luzerne County, *Box 1345, Wilkes Barre, Pennsylvania* 18703 (R18 CA 22190-01)

The pilot detection program is the first effort in implanting a cancer control plan, begun by area physicians several years ago and supported in part by a Cancer Center Planning grant. The program proposes to use specially trained nurse clinicians to perform screening tests and examinations in Luzerne County, Pennsylvania. During the three-year program, nurses will be recruited from the community, trained at Hahnemann Oncologic Institute, and will perform complete screening examinations in two-hospital based clinics. A projected population of 10,944 people over the age of 40 will be screened for cancer of the mouth, throat, cervix, prostate, breast, skin, and rectum.

Demonstration pilot efforts include the training and utilization of nurse clinicians in this unique fashion, studying variables in patient participation, acceptance of nurse clinicians by both patients and physicians, examining the validity and reliability of this form of community based cancer screening, analyzing cost variables and the progressive development of programmatic self-support by the community. The pilot is further designed to encourage the introduction of a single county tumor registry and to encourage additional epidemiologic research in future years, although funds are not requested for these purposes here.

The applicant is the Community Cancer Corporation of Luzerne County (CCC), a new non-profit corporation which has been created to plan and manage this and other cancer related service projects. The corporation and indeed this pilot request are an outgrowth of the extremely high incidence of cancer in the county, the high degree of physician and community support for the project and the potential applicability of the pilot to other similar regions of the country.

THE EPIDEMIOLOGY OF MULTIPLE MYELOMA

S. Grufferman, Duke University, School of Medicine, Dept. of Community Health Science/Pediatrics, *Box 3711, Durham, North Carolina* 27710 (R01 CA 22104-03)

The major objective of this case-control study is to learn more about the epidemiology of multiple myeloma (MM). Surprisingly little is known about the epidemiology of MM, available information is dated, and there are few etiologic hypotheses. To our knowledge, this will be the first case-control study specifically involving MM cases.

The study will have 2 major components, a medical record review of 450 MM cases and an interview study of an additional 150 MM patients, both components involving matched hospital controls. In addition to examining for associations with available demographic variables, associations between MM and socioeconomic class (S-E), occupation, environmental exposures, diet, and diseases causing 'immune stimulation' will be evaluated. Particular attention will be paid to evaluation of the association between S-E class and MM. Paradoxically, MM is reported as being positively associated with high S-E class whereas incidence rates are twice as high in blacks as in whites.

STUDIES OF RADIATION-INDUCED CANCER

C.E. Land, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Field Studies & Statistics Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04481-03 EEB)

The objective of this project is to examine cancer incidence and mortality among populations exposed to ionizing and non-ionizing radiation, especially at low dose levels. Groups studied include Japanese A-bomb survivors, patients exposed to diagnostic and therapeutic radiation, workers with histories of occupational exposures to radiation, and the populations of SEER reporting areas with different levels of solar UV radiation. The listed project members all have individual research interests in radiation-induced cancer. In addition, project members have served on committees and task forces of DHEW, EPA, DOE, NIH, and NCI formulating government responses to current problems associated with health effects of ionizing radiation.

STUDIES OF OCCUPATIONAL CANCER

A.E. Blair, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Occupational Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04480-03 EEB)

This project concerns the identification of cancer patterns within occupational groups that may reflect exposures in the work environment and investigation of methodological issues in occupational studies. Study groups are selected for a variety of reasons including 1) known or potential exposure to established or suspect carcinogenic substances, 2) prior case reports and studies suggesting an unusual cancer experience for the group, 3) requests by outside institutions and 4) availability of useful resources. Resources used include employment and death records maintained by companies; membership and death listings maintained by labor unions and professional organizations; and records from state or federal agencies. Studies during the past year include cohort mortality studies of persons employed in dry cleaning, non-agricultural pest control, chemical plants, non-ferrous smelters, taconite mines, and jewelry manufacturing. Proportionate mortality studies being conducted involve pharmaceutical workers, tobacco workers, petrochemical workers, pottery workers, chromate painters, fur dyers, veterinarians, metal platers, and embalmers. Death certificates are used to investigate occupational origins of leukemia and multiple myeloma, and cancers of the prostate and colon.

2.0673,
RELATION OF PREMORBID PSYCHOLOGICAL FACTORS TO CANCER INCIDENCE

B.H. Fox, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Field Studies & Statistics Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-CP-04414-04-B)

The association of premorbid psychological factors (PPF) -- stress, personality, social environment -- and cancer incidence and mortality has often been reported as present, and occasionally as absent. A theoretical examinaton of the issues in this field was carried out, pointing to possible flaws in the design of most studies, with resulting questions about their conclusions. It further emphasized the need for prospective work. In the present two prospective studies, each member of a cohort, presumed initially without

cancer, will have produced PPF data on entry (1930's to 1960's, and 1958, respectively). Follow-up of cancer death and incidence is in progress and PPF will be related to them. 17-year follow-up of the St. Luke's cohort has yielded the following relationship: Those whose highest score on the MMPI was the depression scale score had a relative risk greater than 2 compared with others in the cohort. The hypothesis that anxiety and depression are related to cancer was not upheld. The theory of the relationship of PPF and cancer is being further pursued in the areas of immune function, life stress, and competing risk.

BIBLIOGRAPHIC REFERENCES: Fox, B.H. Premorbid psychological factors as related to cancer incidence. J. Behavioral Med. 1: 45-133, 1978. Fox, B.H. Sress and cancer. Behavioral Med. 6(6): 19, 1979.

SUICIDE AMONG CANCER PATIENTS

B.H. Fox, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Field Studies & Statistics Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04413-04 FSS)

Suicide rates among cancer patients were determined from the Connectict SEER Cancer Registry and compared with age-matched Connecticut State suicide rates to estimate relative risks. Among male cancer patients a two-fold risk was found, but no excess risk for females. For men, a larger risk appeared the first few years after diagnosis than later. Preliminary data, only partially controlled for other variables, suggest slightly higher risk for ever married than never married, and clearly higher risk among patients with metastasized than in those with localized tumors. Slightly greater risk appears in surgical patients than in those treated otherwise.

CANCER SURVEILLANCE, EPIDEMIOLOGY, AND END RESULTS REPORTING (SEER) PROGRAM

E.S. Pollack, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Biometry Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04254-05 B)

Data on cancer patients diagnosed from year of entry in the SEER Program through 1976 (1973-76 for most participants) were submitted to the NCI by all eleven participants in December 1977. Analysis of cancer incidence revealed considerable variability across all eleven areas. Cancer mortality rates for the total SEER Program are virtually identical with those for the entire U.S. Short-term survival rates for some of the major sites of cancer are amazingly uniform across SEER locations. The SEER Program has been reorganized within the Biometry Branch with a view toward making its operation more effective.

STUDIES OF THERAPEUTIC END RESULTS AND PROGNOSTIC FACTORS

M.H. Myers, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Biometric Research & Analytic Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04257-22 B)

Ten year follow-up results from the HIP study of screening for breast cancer have shown that the screened group experienced 1/3 less mortality from breast cancer than the control group. This reduction appeared to be concentrated in women over 50. The associations of cancer incidence with income and education were studied. Among whites, strong negative associations were observed for esophageal, stomach, lung and cervical cancer with positive associations for colon, bladder and breast cancer. An analysis of TNCS and SEER data showed that for white males the incidence rate of mesothelioma has increased in recent years. The development of methodology for the evaluation of screening programs has demonstrated new age dependent characteristics of lead time and length bias. Appropriate variables to use in the analysis of randomized screening trials were defined. A study of suicides among cancer patients indicated that male patients were at twice their expected risk of suicide while females were not at excess risk. The relationship of the levels of selected urinary steroid metabolites to breast cancer recurrence subsequent to radical mastectomy was studied: relationships were observed only for postmenopausal patients.

CASE-CONTROL STUDIES OF SELECTED CANCER SITES

R.N. Hoover, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Environmental Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04501-02 EEB)

The purpose of this project is to utilize the case-control, interview methodology to do in-depth evaluations of specific cancer sites. By the nature of this method, the exposures evaluated include many of the exposure categories under which other Branch studies are listed; however, either because there are numerous etiologic hypotheses to be tested, or because a tumor deserves an in-depth evaluation in an attempt to generate hypotheses, these types of studies cover a number of different exposure categories, and are therefore considered a separate program area.

STUDIES OF CANCER INCIDENCE AND MORTALITY AND RELATED ETIOLOGIC FACTORS

E. Pollack, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Biometry Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04258-11 B)

During the past year, research on stomach cancer and precursor lesions continued in Japan, Hawaii and Colombia. Research also continued on colorectal cancer in these same areas. International trends in cancer mortalty were analyzed for 42 countries using data from WHO for the time period 1950-1974. Cancer mortality among the Chinese in the United States was examined for the period 1968-1972 and compared with data from 1959-62. The mortality experience of clergymen in five Protestant denominations has been studied and a comparison made between U.S. Episcopalian and British Anglican clergymen. Cancer mortality among Japanese in the United States is being studied at the present time. The Norwegian migrant studies are continuing and a concerted effort is being made to analyze a large set of data in Norway which is expected to produce more useful information on important dietary factors related to gastrointestinal cancers.

CONSULTATION ON CLINICAL TRIALS

D.P. Byar, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Clinical & Diagnostic Trials Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04260-19 B)

The purpose of this project is to provide consultative services in statistical and epidemiological methodology in the design, interpretation, and evaluation of clinical trials and other studies requiring this kind of expertise. For some trials the section provides full statistical support including development of detailed study plans, randomization of patients, collection, processing, editing, and analysis of data, and preparation of scientific papers. At present, members of the section are involved in studies concerned with prostate cancer, bladder cancer, lung cancer, thyroid cancer, breast cancer, testicular cancer, and Mycosis fungoides. Other major consultative activities include membership on advisory committees, grant and contract funding review committees, and review of scientific articles concerned with clinical trials.

CANCER PATIENT DATA CONTRIOL EXPLORATORY STUDIES

S.H. Walker, Colorado Regional Cancer Center Inc., *1655 Lafayette St., Suite 301, Denver, Colorado* 80218 (R10 CA 21878-03)

The objective of this project is to develop an operational plan and mechanisms for the Colorado Regional Cancer Center Data Control System to include standardized input of statistical data, computerized processing, quality control procedures, statistical analysis, and reporting. The Data Control System will facilitate evaluation of Cancer Center activities, provide the capability of sharing data with other Cancer Centers, and support epidemiological and clinical research activities in institutions affiliated with the Colorado Regional Cancer Center, Inc. Activities will support the establishment of the 'Statistical Data Base of a Comprehensive Cancer Center,' as specified in objectives established by the National Cancer Advisory Board for the Cancer Centers Program. Assessing patient load, referral patterns, incidence and etiology of various neoplasms, and effectiveness of treatment programs in numerous institutions will be facilitated by implementation of the Data Control System.

CLASSIFICATION AND ETIOLOGY OF CHILDHOOD BRAIN TUMORS

A. Leviton, Childrens Hospital Medical Center, *300 Longwood Ave., Boston, Massachusetts* 02115 (R01 CA 21819-03)

This is a case-control epidemiologic study of brain tumors occurring in children. Cases are those children (ages 1 day to 16 years) with a brain tumor who reside in the catchment area of eight "cancer' registries included in the S.E.E.R. program. Three controls will be selected for each case by random digit dialing, matching for age, (plus or minus 3 years), sex and race. A one and one-half hour long questionnaire will be administered to both parents by an interviewer in the parents' home. The questionnaire includes requests for information about demographic features, parents' exposure to possible teratogens

and mutagens, familial history of tumor and birth defects, and exposure to infectious agents. During this project, questionnaires will be completed for approximately 400 cases and 1,200 controls. This sample size is expected to be sufficient for the study of two of the most common (groups of) tumors (cerebellar gliomas and medulloblastomas).

A CANCER CENTER EPIDEMIOLOGY BIOSTATISTIC UNIT

M.D. Keller, Ohio State University, Columbus Campus, School of Medicine, Dept. of Prev Med, *370 W. 9th Ave., Columbus, Ohio* 43212 (R10 CA 21751-03)

The OSUCCC is developing an Epidemiologic/Biostatics Laboratory whose internal and external data systems will be compatible with the National and Local cancer patient data systems. This Minimum Cancer Patient Dataset (MCPD) will afford interchange and exchange of data and information with other National Cancer Centers based on the Computerized Cancer Patient Data System (CCPDS).

The local data and information storage will be designed to facilitate patient data retrieval, patient care and therapy, protocol evaluation, and epidemiologic and biostatical evaluation as well as functioning as a tumor registry for the OSU Hospitals and community hospitals incorporated into the data bank.

CANCER CENTER SUPPORT GRANT

J.W. Steiner, Illinois Cancer Council, *36 S. Wabash Ave., Suite 700, Chicago, Illinois* 60603 (P30 CA 21742-02)

The Center received Core support on December 1, 1978. A full-time director assumed his responsibilities on January 1, 1979.

Staffing has progressed in accordance with the plan. An Associate Director for Clinical Programs, and Assistant Program Directors for Rehabilitation, Biostatistics, and Epidemiology were hired. A search for an Associate Director for Cancer Control is in process.

The highest priority for development is in the Clinical Research area. Applications have been prepared for an R01 and a P01 project, and development of a number of inhouse protocols has been initiated. The Gynecologic Oncology Group program began accessing adequate numbers of patients so as to merit the submission of an application for funding this regional project.

The Division of Research Resources has been actively developing computer programs to assist the activities of the Protocols Office. The development of the database has progressed actively and specialized modules are being planned to subserve subsequent research projects. Epidemiological studies have been planned or are in progress to include the mapping of potential risk areas in the state, a study of a cohort of Latinos in Chicago who are in transition from a low to a high colon cancer area, etc. The Cancer Information Service has continued functioning and is beginning to benefit from the Cancer Information Needs Study which is in progress. A community oncology program is in an advanced stage of planning, involving hospitals in the community which are not connected with a university. The educational endeavor has centered largely on gap areas in oncology nursing education and in pediatric nursing education.

2.0685,

ENVIRONMENTAL EPIDEMIOLOGIC STUDY OF PANCREATIC CANCER

L. Gordis, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R26 CA 21642-03)

Since pancreatic cancer is now the fourth leading cause of cancer death in the United States, intensive efforts are needed to reduce the impact of this disease. In view of the rapid clinical course of pancreatic cancer and the grim prognosis, it is likely that the greatest hope for progress in treatment of this disease will be through prevention and early detection. A three-part environmental epidemiologic study of pancreatic cancer is therefore proposed to identify specific risk factors and possible etiologic agents and mechanisms. The first phase will describe the changing incidence and mortality of pancreatic cancer over a 15 year period in a defined community, metropolitan Baltimore. The second phase of this study will be a case-control investigation of pancreatic cancer patients and various control groups to explore possible etiologic factors, in particular, environmental and occupational characteristics including exposure to chemical agents and to health care environments and occupations. In addition, younger and older cases will be compared with respect to these characteristics, to determine whether pancreatic cancer in the young is the same as in the old. Finally, a non-concurrent prospective study will be carried out to determine whether the risk of developing or dying from pancreatic cancer is higher in patients with chronic pancreatitis than in a non-pancreatitis control group. The approaches outlined above are designed to provide the basis for modifying environmental exposures and thus developing measures for preventing the disease. Secondly, the results may permit the identification of populations which are at high risk for the disease who might benefit from close medical surveillance and intensive efforts at early detection using the newer diagnostic techniques currently being developed.

STUDIES OF UTAH COLORECTAL CANCER FAMILIES

E.J. Gardner, Utah Higher Education System, Utah State University, School of Science, Dept. of Biology, *Main Bldg., Office 104, Logan, Utah* 84321 (R26 CA 21623-02)

These studies are designed to follow the development of adenomas and carcinoma in people with inherited predisposition to familial polyposis and the Gardner syndrome, to define indexes that represent phenotypic expressions of preneoplasia, and to predict carriers of the gene defect before clinical signs appear.

During the initial phase of this project, members of three kindreds having varying degrees of expression of familial polyposis and the Gardner syndrome were studied. The subjects were examined and classified into categories, including those having known Gardner syndrome with expression of polyposis and extracolonic manifestations (osteomas, fibromas, epidermoid cysts, desmoid neoplasms, odontomas, and supernumerary teeth); polyposis without extracolonic manifestations of disease; indeterminate Gardner syndrome with extracolonic manifestations but without polyposis; potential carriers of the gene defect known to be asymptomatic progeny of an affected parent; members of kindred branches that were polyposis and cancer free for three or more generations; additional control subjects.

These characteristics were identified in members of familial aggregates. In addition, initial examination of biopsy specimens of colonic mucosa revealed the presence of chronic inflammatory disease consistent with ulcerative colitis in four siblings of a familial group. Multiple gastric polyps were present in two siblings, and duodenal adenomas were found in other subjects. Distal esophagitis was present in three subjects whose ages were 16-21 years, with distal esophageal polyps present.

Further measurements are now underway in the continued examination of these subjects, and intestinal, cutaneous, and blood specimens are being analyzed for measurement of growth charcteristics of cells, enzyme activities, and recognitive immunity. Patterns of inheritance of abnormal phenotypic attributes are being studied in symptomatic subjects, and in those who are potential carriers of the genetic defect leading to familial polyposis and Gardner syndrome.

2.0687,

RADIATION-INDUCED THYROID CANCER

A.B. Schneider, University of Chicago, Michael Reese Hospital & Medical Center, Dept. of Medicine, *2929 S. Ellis Ave., Chicago, Illinois* 60616 (R01 CA 21518-04)

The major objective of this research proposal is to study radiation-induced thyroid cancer by a coordinated program of clinical and basic endocrinological investigations. The clinical studies are designed to determine the current risk and continuing incidence of radiation-induced thyroid cancer and to evaluate methods of diagnosis and medical and surgical approaches to treatment. This will be accomplished by a longitudinal study of patients who have been evaluated at Michael Reese Hospital because of a history of childhood head or neck irradiation. Of 5,200 patients who were so treated, 1,700 have been examined and another 1,400 have been contacted. In this population there is a 32% prevalence of nodules and among those who have had surgery 36% have had thyroid cancer. Follow-up examination of patients who were initially normal will provide an estimate of the continuing incidence of radiation-induced thyroid cancer. Follow-up examination of patients who were initially abnormal will provide an evaluation of the various methods of treatment which have been used. Together these will provide the information necessary to develop clinical guidelines for the care of persons with a history of head or neck irradiation.

Laboratory studies will focus on the role of plasma thyroglobulin in the diagnosis of thyroid tumors. Plasma thyroglobulin is elevated in a majority of patients with thyroid nodules and in 12% of patients who have a history of irradiation but who otherwise appear completely normal. This project will determine whether an elevated thyroglobulin level indicates an especially high risk for the formation of thyroid nodules.

We will continue our detailed studies of the molecular properties of plasma thyroglobulin using physical-chemical methods in order to improve its diagnostic usefulness and to understand how it enters the circulation. The Wollman transplantable thyroid tumor line 1-1C2 will be used as a model system for the study of plasma thyroglobulin and thyroid cancer.

SCREENING FOR NEOPLASMS IN IRRADIATED POPULATIONS

L.H. Hempelmann, University of Rochester, School of Medicine & Dentistry, Dept. of Radiology, *601 Elmwood Ave., Rochester, New York* 14627 (R01 CA 21452-03)

This population of 606 women treated with x-rays for acute post-partum mastitis and their controls (554 sisters; 539 women with post-partum mastitis not treated with x-rays, and their 206 sisters) have been followed by mail questionnaire since 1955. The irradiated women have an increased risk of developing breast cancer. This application proposes continuation of the mail health survey, the review of histopathology of the breast cancers experienced by the treated women and the controls, and periodic mammograhic-thermographic screening of the treated women and eligible controls (NCI guidelines).

THE EPIDEMIOLOGY OF CHILDHOOD RHABDOMYOSARCOMA

S. Grufferman, Duke University, School of Medicine, Dept. of Pediatrics, *Box 3711, Durham, North Carolina* 27710 (R01 CA 21244-02S1)

An incidence survey of childhood rhabdomyosarcoma (RMS) has been conducted covering the State of North Carolina during the period 1967-1976. This was initiated by the clinical observation of a possible 'epidemic' of RMS in the state. Preliminary data suggest that rather than an epidemic, there has been a 'straight-line,' almost 4-fold increase in RMS incidence over the 10-year study period. The incidence rate reached is greater than previously reported estimates based on mortality statistics but the same as estimated incidence data from the Third National Cancer Survey. It also appears that males are affected more than females (M/F equals 1.7) and blacks more than whites (B/W equals 1.3). In previous studies the excess of males was less marked (M/F equals 1.0-1.4) and whites experienced higher risks than blacks. case-control approach is currently being used to study the 'descriptive epidemiology' of RMS as well as associations between RMS and potential antenatal, childhood, familial, dietary and environmental etiologic exposures.

EXPLORATORY STUDIES ON CANCER PATIENT DATA CONTROL

R.L. Prentice, Fred Hutchinson Cancer Research Center, *1124 Columbia St., Seattle, Washington* 98104 (R10 CA 21193-03)

This proposal is to continue the development of a clinical data base for the Fred Hutchinson Cancer Research Center. Uniform data are obtained on approximately 1300 new patients per year who receive treatment in the Adult Leukemia Center, The Children's Orthopedic Hospital or at any of six affiliated oncology units. The data collected include both the SEER (Surveillance Epidemiology and End Results) data and the CCPDS (Centralized Cancer Patient Data System) minimal data. The proposed work includes local uses of the data, participation in collaborative uses of CCPDS patient data and the provision of statistical support to local therapy studies.

STUDIES ON CANCER PATIENT DATA CONTROL

J.E. White, Howard University, School of Medicine, Dept. of Oncology, *2400 6th St. N.W., Washington, District of Columbia* 20001 (R10 CA 21185-04)

Grant support is requested for continuation of the Centralized Cancer Patient Data System program at the Howard University Cancer Center (HUCC). All patients with malignant neoplasms seen at Howard University Hospital have entered in the Centralized Cancer Patients Data System (CCPDS) since July 1, 1977. The present grant has proved to be of immense value in establishment of a computerized data base on all cancer patients. As of September, 1979 HUCC has submitted to the CCPDS data on 664 new cancer cases and follow-up data on 399 cases. The proposed grant will ensure the continuity and further refinement of the data collection activities at the Howard University Cancer Center and its participation in CCPDS.

CANCER IN ARSENIC EXPOSED POPULATIONS

P.E. Enterline, University of Pittsburgh, Graduate School of Public Health, Dept. of Biostatistics, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (R01 CA 20540-03)

The mortality experience of workers at a copper smelter at Tacoma, Washington, producing nearly all the arsenic trioxide produced in the United States will be studied. Men employed for a year or more since January 1, 1940, will be followed for deaths through December 31, 1975. The cancer mortality experience of this cohort will be related to duration and intensity of arsenic exposure and latent period. Both historic atmospheric measures of arsenic and urine arsenic testing of workers will be used to estimate exposures. In addition, the mortality experience of persons living near the smelter will be studied to see if any effect of atmospheric contamination on cancer mortality can be detected. This will include follow-up on children from an elementary school in the area using school records dating to 1910. Also included is a study of mortality in the area adjacent to the smelter where elevations in urine arsenic have been found, apparently related to the smelter.

EPIDEMIOLOGIC STUDY OF OVARIAN CANCER

P. Greenwald, State Bureau of Cancer Control, Division of Epidemiology, *Empire State Plaza, Tower Bldg. Rm. 565, Albany, New York* 12237 (R01 CA 20502-03)

Our general objective is to determine, by means of a concurrent case-control study, whether risks of various histologic types of ovarian cancer are influenced by: a) prior reproductive experience of the patient, b) cancer among first degree female relatives, c) a combination of these factors. The hypothesis that low fertility or infertility contribute to risk will be refined and assessed. Also, we will have a systematically derived and validated statement of familial risk among first degree female relatives. Additional study variables will include prior hormonal therapy, pre-existing medical conditions and menstrual history.

In the proposed study, two population controls will be selected for each ovarian cancer patient interviewed. The controls will be matched by age and county of residence. Demographic and clinical data will be collected from hospital records of each ovarian cancer patient, and pathology slides reviewed. Various types of epidemiologic data will be collected through face-to-face interviews with each patient and control. Standardized follow-up procedures have been developed for verifying whether or not the relatives have ever been diagnosed with or died from a malignancy.

CANCER IN PERSONS EXPOSED TO EXOGENOUS ESTROGENS

J.W. Meigs, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (R01 CA 20347-04)

This retrospective-prospective study will identify mother-offspring pairs where prenatal estrogen exposure occurred and will determine the cancer incidence among these mothers and offspring. Two control groups of mother-offspring pairs will be identified and the cancer incidence among these women and their offspring will be compared to that in the at-risk group. One group will be based on physician-matched controls, the second control group will be selected using Connecticut birth registration data.

Cancer experience will be determined through linking the names of members of the cohorts to patients reported to the Connecticut Tumor Registry. All cancer sites will be considered with particular attention to reproductive system cancers.

To date, more than 900 exposed mother-offspring pairs and 700 physician-matched control pairs have been identified and detailed information has been abstracted from their prenatal records and related birth certificates. These activities have been accomplished for an additional 100 unmatched physician controls. A second control group of 1150 mother-offspring pairs had been selected. All study mothers have been followed through the use of City Directories to determine person-years-at-risk.

EVALUATION OF THE TYPES AND CAUSES OF INFECTIOUS DISEASES IN CANCER PATIENTS

S.C. Schimpff, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Section of Infection Research, *Baltimore, Maryland* 21201 (Z01 CM 06264-10 COB)

Infection is the leading cause of morbidity and mortality in patients with acute leukemia and a major cause in other types of advanced malignancies such as Hodgkin's disease and oat cell carcinoma of the lung. The aims of this project are to catalogue and identify the infections, identify the predisposing factors and evaluate new techniques for more rapid and/or accurate diagnosis of infection. This program has been in progress for over eight years and has allowed meaningful evaluation of the types of infection occurring in different types of tumor patients. Specific problems have been identified such as the nature of hospital acquisition of potential pathogens including bacteria and fungi. This epidemiologic data has allowed appropriate and logical development of infection prevention techniques and application of newer methods of infection diagnosis such that there has been a reduction of infection morbidity and mortality.

STUDIES ON ONCOGENIC HERPESVIRUSES OF MAN AND SUBHUMAN PRIMATES

J.M. Easton, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Clinical Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-CP-04849-06-LVC)

Work was continued on the American Nasopharyngeal Carcinoma Registry. New cases submitted to the Armed Forces Institute of Pathology and the Clinical Studies Section were accessioned. On the basis of the literature, U.S. NPC cases and those from other countries were compared histologically. Data from the Third National Cancer Survey and the Surveillance, Epidemiology, and End Results Program demonstrated a high incidence of NPC in young blacks. This young black peak may be comparable to similar NPC peaks in the Tunisian and East Indian populations. A comparison of data on young and old patients with NPC, described in 'Cancer In Five Continents,' suggests that there may possibly be different etiologies in different age groups.

IMMUNOLOGIC FACTORS IN CANCER ETIOLOGY

R.N. Hoover, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Environmental Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-CP-04401-03-EEB)

The purpose of this project is to identify and study populations with altered immunologic states experiencing unusual rates of malignancy. Risks of cancer of different sites are quantified for various groups of such patients, compared with each other, and characteristics and possible determinants of unusual risks are sought. The populations studies include renal transplant recipients, patients with inherited and acquired immune deficiency syndromes, groups of immune-stimulated persons (e.g., hyperimmunized, autoimmune syndromes) and patients experiencing conditions for which sequelae related to immunity are suspect but unknown (e.g., splenectomy patients). Both cohort studies of these groups of patients and case-control studies of such patients who also developed cancer are conducted.

U.S. CANCER MORTALITY SURVEY

T.J. Mason, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Environmental Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-CP-04378-03-EEB)

The objective of this study is to examine the cancer mortality experience in the United States relative to cancer etiology. Special emphasis is placed upon the selection of areas in the U.S. for intensive study. Publications from this area of interest have facilitated the design of ongoing analytical investigation to test specific etiologic hypotheses. An analysis of prostatic cancer mortality rates suggested that environmental exposure related to urban living may account for the predisposition of American blacks to this tumor. Respiratory cancer mortality, 1950-69, was consistently high in U.S. counties where shipyards were engaged in the construction and repair of large naval and cargo vessels during World War II. When cell types of leukemia for 1968-71 were analyzed, some clustering of acute myeloid leukemia was seen in the central United States. Ethnic susceptibility appears to account, at least in part, for the regional clustering of kidney cancer and may provide leads to environmental determinants. We are continuing to expand our data sets, both of reported deaths and measures of exposure.

STUDIES ON PSEUDOMONAS AERUGINOSA IN A CANCER RESEARCH PROGRAM

M.R. Moody, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Microbiology Section, *Baltimore, Maryland* 21201 (Z01 CM 06223-10 COB)

Pseudomonas aeruginosa is one of the chief causes of infection in patients with acute leukemia and other severe malignancies whose white blood cell counts are less than or equal to 1000/ml. The prime objective of this study has been to monitor the epidemiology of P. aeruginosa in cancer patients and to study its host-parasite interaction and susceptibility to antibiotics. Recovery rates are lower than in previous years. Serotyping of the 66 P. aeruginosa strains recovered from 21 patients revealed that only two patients had multiple serotypes (2) present. No transmission of P. aeruginosa between patients could be detected. The identification schema developed in our laboratory to speciate pseudomonas strains other than P. aeruginosa continues to be successfully used. A schema for identification of less common non-sacchardytic Pseudomonas and Alcaligenes spp. has now been successfully evaluated with 200 strains of these species. Studies of non-agglutinating pseudomonas antibodies have been temporarily postponed.

BIBLIOGRAPHIC REFERENCES: Moody, M.R., Kessel, R.W., Young, V.M., Fiset, P. The role of nonagglutinating antibody in the protracted immunity of vaccinated mice to Pseudomonas aeruginosa infection. Infection and Immunity 21: 905-913, 1978. Moody, Marcia R. and Young, Viola M. A Comparison of antibiograms of non-aeruginosa pseudomonads recovered in two locales. J. Antimicrob. Chemother. 5: 143-149, 1979.

FAMILIAL, CONGENITAL AND GENETIC FACTORS IN MALIGNANCY

J.J. Mulvihill, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Field Studies & Statistics Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04377-08 CEB)

Study of genetic diseases with neoplastic manifestations and detailed investigation of families with high risk of cancer may help detect environmental and genetic influences in carcinogenesis, especially when appropriate laboratory assays are used.

Besides results from the Clinical Studies Section, clinical reports were made on three cancer families and a series of patients with rhabdomyosarcoma complicating neurofibromatosis. Special emphasis was placed on laboratory approaches to cancer families. The heritability of SV40 T-antigen in 26 families and the frequencies of chromosomal abnormalities and sister chromatid exchanges in five families were reported. In one family with acute myelogenous leukemia, patients with malignancies had abnormal sensitivity of fibroblast to gamma-radiation, whereas tumor-free relatives had normal sensitivities. Abnormal in vitro response to pooled alloantigens was a consistent abnormality in family members with the B-K mole syndrome (and some spouses). We continue to seek animal models for human, congenital and genetic disease, and will follow the same approach, using new laboratory methods and epidemiologic clues from other sources as available.

ROLE OF DIETARY LIPIDS IN INCREASED INCIDENCE OF MAMMARY CANCER

W.R. Kidwell, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Cell Cycle Regulation Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CB 08229-03 LPP)

Epidemiological and experimental studies have implicated high dietary fat in the increased incidence of mammary cancer. Experimental systems have been established for assessing fatty acid effects on the growth of cells from normal tissue and carcinogen induced mammary tumors of rats. The studies show that all unsaturated fatty acids present in the gland in appreciable amounts promote cell growth. Both normal and tumor cells are inhibited by saturated fatty acids. Maximum growth rate of tumor cells is obtained with oleic acid while normal cells grow best in the presence of linoleic or linolenic acid. Both normal and tumor cells may be able to recruit fatty acids needed for growth from neighboring tissue. Perphenazine treatment of animals produces an increase in the relative amount of unsaturated fatty acids in the mammary gland but not in omental fat. This appears to be effected by the action of prolactin. Maps of fatty acid types at various distances from growing mammary tumors have been made. These suggest a concentration of unsaturated relative to saturated fatty acids closest to the tumors.

FIELD STUDIES IN HIGH-RISK AREAS

W.J. Blot, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Analytical Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04779-03 EEB)

The objectives of this project are to identify and describe the environmental determinants of cancer in areas of the U.S. at high risk of cancer through the use of analytic epidemiologic techniques. Toward this end a series of case-control studies has been initiated to test a number of hypotheses regarding the origins of cancer. Presently ongoing are interview studies of lung cancer in northeast Florida; mesothelioma in tidewater Virginia; esophageal cancer in Washington, D.C.; nasal and oral cancer in parts of the South; renal cancer in Minnesota; lung, pancreas, and stomach cancers in southern Louisiana; and lung cancer in eastern Pennsylvania. All areas are at high risk for these tumors. Interviewing was completed during the year for studies of colon cancer in rural Nebraska and lung cancer in coastal Virginia, and data analysis is in progress. A random telephone survey of smoking habits in Georgia showed no coastal excess, highlighting the importance of industrial factors (particularly shipbuilding) in the clustering of lung cancer along the coast, identified by a case-control study of this tumor completed during the year.

PLANNING AND DEVELOPMENT IN CANCER EPIDEMIOLOGY

R.W. Miller, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Field Studies & Statistics Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04325-16 CEB)

The objectives of this undertaking are to originate new epidemiologic approaches to the study of cancer causation in man and animals, to develop sources of data related to specific epidemiologic problems, to stimulate epidemiologic research in other health agencies and to develop an on-the-job training program for medical and statistical officers. Opportunities for research in cancer epidemiology are based on questions arising from clinical or laboratory observations, on unusual groupings of cancer cases in the population, and on study of the characteristics of groups of persons prior to the onset of a specific type of cancer as compared with similar persons who have not developed the disease. In parallel with this, plans are made for on-the-job training in cancer epidemiology for research physicians, veterinarians, and statisticians.

SPECIAL NON-MELANOMA SKIN CANCER INCIDENCE SURVEY AND EPIDEMIOLOGY STUDY

J. Scotto, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Biometry Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01-CP04475-03-B)

This project, a collaborative effort by the NCI, EPA and other federal agencies, was initiated to provide more data relative to skin cancer and harmful solar ultraviolet. An urgent need for these data has existed since recent scientific reports have warned about the decomposition of stratospheric ozone by nitrogen oxides and chlorofluoromethanes (CFMs). Federal regulatory agencies have already recommended bans on the use of aerosol spray cans which use CFMs as propellants. In the near future, there will be critical reviews of all pertinent information by government as well as individual interests concerned with the threat of increased human skin cancer due to excess amounts of UV-B reaching the earth's surface, as its protective ozone shield is depleted. As mandated by Public Law 95-95 (amendment to the Clean Air Act of 1977), the NCI will continue its investigations by adding 2 new locations to its data bases during this fiscal year. This will provide more reliable national estimates of the degree of morbidity from nonmelanoma skin cancer as well as epidemiologic data on host and environmental factors, other than solar ultraviolet, associated with increased risk. New leads from 8 surveys just being completed will be pursued in two new surveys being implemented.

CLINICAL STUDIES SECTION, BOSTON, MASSACHUSETTS

F.P. Li, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Field Studies & Statistics Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04400-18 CEB)

The staff of the Clinical Studies Section in Boston, Massachusetts has sifted a large volume of clinical data to identify patients for etiologic studies. These unusual patients are usually found through attendance at clinical conferences and rounds, and through special referrals. With informed consent, epidemiologic studies are made of the environmental and genetic background and laboratory studies are conducted to clarify biologic mechanisms of carcinogenesis. At present, several family aggregates of cancer are under study, e.g., Turcot's syndrome in two families; Gardner's syndrome variant; breast cancer-Hodgkin's disease aggregation; autosomal dominant renal cell carcinoma associated with a 3:8 chromosome translocation. In addition, a family suffering from mesothelioma following asbestos exposure at a shipyard has prompted two studies of mesothelioma and lung cancers in two New England shipbuilding communities. Also, a computerized Registry of Survivors of Childhood Cancer has been established through collaboration of the Clinical Studies Section with the Sidney Farber Cancer Institute. The 600 registrants represent approximately 2% of all survivors of U.S. childhood cancer in the last two decades. Patients in the series are being studied for second malignancies, cancer in close relatives, and genetic effects in progeny.

METHODOLOGIC STUDIES IN EPIDEMIOLOGY

W.J. Blot, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst., Analytical Studies Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 CP 04500-02 EEB)

The objectives of this project are to develop, adapt, expand, and evaluate methodological procedures useful in epidemiologic studies of cancer. Methods of design and analysis of epidemiologic studies were given particular emphasis with attention focusing on the adaptation of multivariate logistic models for analysis of case-control data. Texts on statistical methods to analyze epidemiologic data were authored, and the Branch coordinated publication of a journal issue on biostatistical methods in cancer research in the U.S and Japan. Investigation of general epidemiologic techniques for studying environmental cancer continued, including reviews of methods to evaluate the magnitude of low-dose radiation risks.

EPIDEMIOLOGY OF LIVER CANCER IN TEXAS

R.A. Buffler, University of Texas, Health Science Center at Houston, School of Public Health, Dept. of Epidemiology, *6515 Freeman, Houston, Texas* 77025

Study mortality from primary liver cancer in selected counties in Texas which were selected because they have the highest rates of primary liver cancer in this country. Use a case-control approach selecting two controls for each caseof primary liver cancer from the next deaths which occur that match on age (within the same five-year age category), sex, and race. The occupation and industry of employment will be coded from death certificates, and, in addition, information regarding employment and exposure in specific industries. Concentrate on Orange and Jefferson counties due to the large percent of the workforce employed in chemicals and related manufacturing industries. The study will include analysis of data for Orange and Jefferson counties, including a detailed review of occupational histories and available pathology, plus additional studies from the results from Brazoria County.

ETIOLOGIC STUDY OF RESPIRATORY CANCER IN COASTAL TEXAS

P.A. Buffler, University of Texas, Health Science Center at Houston, School of Public Health, Dept. of Epidemiology, *6515 Freeman, Houston, Texas* 77025

Make recommendations regarding the design of this study, including evaluations and alternative case and control identification. Identify the respiratory cancer cases and controls. Abstract information on date of diagnosis, method of confirmation, and histologic type from medical records of the cancer cases. Produce an adaptation (to the local situation) of an existing questionnaire previously used by the EEB. Locate the cases and controls, or appropriate representatives, and conduct personal interviews with them using the adapted questionnaire. Assist in decisions on the advisability of follow-up on those difficult to locate or refusing interview. Field edit the finished questionnaires for completeness and accuracy. This should include a telephone follow-up of a random sample of respondents. Identify the location of each oil refinery, chemical manufacturing plant, and shipyard in the six-county area. Code the location of these plants and of each residence recorded in the interviews. Make recommendations for analyses of the data.

INVESTIGATION OF POSSIBLE CORRELATIONS BETWEEN MORPHOLOGICAL AND EPIDEMIOLOGICAL CHARACTERISTICS OF BREAST CANCER

B. Stenkvist, University Hospital, Dept. of Clinical Cytology, *75014 Uppsala, Sweden* (CB-53854-S)

SCOPE: To ascertain possible correlations between the morphologic variables and the established epidemiological risk factors of breast cancers. The results may be applied not only to identify individuals at high risk of breast cancer but may be used prognostically to predict course of disease. This prospective study will consist of two phases: Phase I will consist of a pilot study of histopathologic material from 110 breast cancers from four counties in Sweden utilizing the computerized Central Swedish Cancer Registry. The tumors will be classified histologically according to WHO (Scarff and Torloni 1968) and Acherman's classification (1970). Another aim of this project is to make a quantitative evaluation of a number of morphological characteristics by computer analysis of tumor cell populations utilizing a Leitz MPVII scanning photometer connected to a PDP-8 computer with 24k of core, and relate these to the standard classification. Planning for the epidemiologic data will be collected on each patient and computerized. Under Phase II, statistical analysis of the data will be made with application of the newly acquired morphologic classification to the epidemiologic variables.

RISK IN DIAGNOSIS OF NON-INVASIVE MAMMARY CARCINOMA

D.L. Page, Vanderbilt University, School of Medicine, Dept. of Pathology, *21st Ave. S. & Garland, Nashville, Tennessee* 37232

Determine the specific risk of an individual patient, or group of patients, given specific information about anatomic changes in the breast as well as nonanatomic risk factors. Identification of anatomic risk factors at a given point in time with extended follow-up of the patients showing different changes is the most definitive available method for specific assignment of risk. This study design, allowing comparison of the incidence of subsequent breast cancer in women with confirmed benign lesions and appropriate control group(s) is essentially a prospective study as women enter the study with a finding 10-25 years prior to the time of follow-up. This is a prospective study conducted in retrospect. Neither the case-control comparison of the frequency of types of breast disease in women who developed cancer nor the study of concurrent changes found in breasts containing carcinomas may achieve the aim proposed by this study.

EPA/NCI SPECIAL SKIN CANCER EPIDEMIOLOGY STUDY

M. Berlin, Westat Inc., *11600 Nebel St., Rockville, Maryland* 20852

OBJECTIVES: Assist NCI in the development of materials and procedures for the Minneapolis pilot test. Conduct general population surveys in each of four selected areas of the TNCS. Design and draw a probability sample of telephone numbers which will be called to identify private residences. Conduct interviews with at least one adult member of the household at each residence. An estimated 500 households will be surveyed. Conduct additional general population surveys in the seven SEER areas. The sample size of 500 cases and survey procedures are planned to be the same as those used for the TNCS area surveys. However, in certain age/sex classes, an estimated 500 area sample cases will be analyzed for case control comparisons between the general population interviews and interviews with selected cancer patients. Conduct telephone interview surveys with patients in the seven SEER areas. The sample size will be 500 patients per survey area. These surveys will be dependent upon agreements between the SEER contractors and the NCI.

EPIDEMIOLOGY OF BENIGN BREAST DISEASE

B. Modan, Chaim Sheba Medical Center, *Bitan 27, Tel Hashomer, Ramat Gan, Israel*

OBJECTIVE: To attempt to determine the characteristics of patients with different types of noninvasive breast lesions, with particular reference to those factors reputed to be preferentially associated with breast cancer, and to compare the findings with our similarly conducted breast cancer study. The proposal consists of two phases: case-control interview study of 600 cases of noninvasive breast disease, and an incidence study of noninvasive breast lesions in a total community. In both phases, particular attention will be paid to the relative frequency of distinct histo-pathological forms in high and low risk sub-populations for breast cancer, i.e., European vs. Asian and African born. The characterization of the breast lesions will take into account the histological pattern, degree of atypia, and lymphoreticulo-endothelial response (LRE).

STUDY OF ETIOLOGIC FACTORS FOR LUNG CANCER

J.E. Davies, University of Miami, School of Medicine, Dept. of Epidemiology & Public Health, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152

OBJECTIVES: 1. Identify certain patients who will be hospitalized in Jacksonville during a one-year period beginning when the contract is let. The patients will include all males newly diagnosed as having lung cancer, and 2 age-, sex-, and race-matched controls admitted to the same hospitals for conditions other than lung cancer or lung disease. The hospitals from which the lung cancer cases and controls will be identified are Baptist Memorial, Jacksonville General, Jacksonville Beach, Memorial Hospital of Jacksonville, Methodist, Riverside, St. Luke's, St. Vincent's, University Hospital of Jacksonville,and the U.S. Naval Medical Center. 2. Identify all cases of asbestosis and mesothelioma diagnosed in these hospitals during 1970-77. 3. Obtain approval from each of these hosptials, and from any other body from which approval is necessary, to conduct a case-control interview study of cancer among these patients. 4. Obtain slides of lung tissue and other relevant material for all lung cancer and mesothelioma cases so that each can be reclassified as to cell type.

SAN FRANCISCO RESOURCE FOR CANCER EPIDEMIOLOGY

D.F. Austin, State Dept. of Health, *714 P St., Sacramento, California* 95814

Maintain a cancer reporting system in the five counties of the San Francisco-Oakland metropolitan area.

The system will utilize standardized abstracts of records on all cancer patients seen in the 75 hospitals in the area as well as for all five-county area resident patients who are diagnosed or treated in hospitals in other areas for active cancer. All death certificates of residents dying in the area or outside the area where cancer is mentioned on the death certificate as well as the death certificate of any case listed in the registry will be abstracted. Records of private laboratories and radiotherapy units will be utilized in order to insure complete coverage of cases. Records of nursing homes which provide the services of diagnostic physicians and/or laboratories to patients will also be utilized. Reporting and data processing procedures are to be maintained so as to produce valid incidence rates within eleven months after the end of each calendar year.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Cancer Inst. $2,240,743

2.0729,

EPIDEMIOLOGIC STUDY OF POPULATIONS PREVIOUSLY EXPOSED TO HEXACHLOROBENZENE

R. Hoover, University of Wisconsin, Madison Campus, Graduate School, *500 Lincoln Dr., Madison, Wisconsin* 53706 (PROJECT #18)

In several eastern villages near Dyarbarkir, Turkey during a 3-year period from 1956-1959, about 4,000 people were inadvertently exposed to hexachlorobenzene (HCB) employed as a herbicide for seed grains used as food sources. Several adults and children died from acute toxicity. Those surviving developed neurologic and cutaneous problems. A description of this episode was provided by Peters, et al., and they concluded that HCB exposure was causative of this episode. Formerly exposed populations continue to be symptomatic. It appears that sufficient subjects from initial exposure cohorts are yet alive for follow-up study. Additionally, records of those initially exposed who have died in the past 20 years are available for mortality ascertainment. The exposed population is largely closed, having little in- or out-migration patterns. What, if any, long-term human effects may be associated with HCB exposure will be investigated.

The purpose of this study are to: 1) determine mortality characteristics of previously registered HCB victims; 2) determine HCB maternal milk, fat, and plasma concentrations of HCB in present survivors and children born since 1955; 3) ascertain current health status of present HCB-exposed survivors and their children; 4) study absorption, distribution, biotransformation, and excretion characteristics of HCB and derivative metabolites in experimental animals.

Mortality data of previously known HCB victims will be obtained, collected, and tabulated by age, sex, place of residence, and primary and secondary causes of death. These will be compared in a retrospective manner with similar data of individuals from the same general locale not exposed to HCB. Gas chromatography will be employed to quantitate HCB levels in maternal milk, fat, and plasma of present survivors and children born since 1955. Ascertainment of their current health status will be made by physical and chemical examination procedures. Special effort to investigate teratogenicity, oncogenicity, mutagenicity, behavioral changes, adverse reproductive phenomenon, etc., will be made. A study of the absorption, distribution, biotransformation, and excretion of HCB and derivative metabolites in experimental animals will be conducted.

NCI/EPA EPIDEMIOLOGICAL STUDIES OF LUNG CANCER IN COMMUNITIES WITH NONFERROUS SMELTERS

W.J. Blot, Lehigh University, Center for Social Research, *10 W. 4th St., Bethlehem, Pennsylvania* 18015 (PROJECT #10)

Exposures to inorganic arsenic in nonferrous smelters are thought to induce lung cancer. A recent correlational study has raised the suspicion that a communitywide risk from arsenical air pollution may exist within counties where the smelters are located.

A case-control epidemiologic study of lung cancer is planned to sort out the roles of occupational exposures, general environmental exposures, and cigarette smoking in relation to the excess risk of lung cancer in nonferrous smelter counties. The study is being conducted in eastern Pennsylvania where a large work force is employed in the smelting of zinc ores. Recent (within 5 years) lung cancer cases and controls will be identified, and they, or their next-of-kin in the event they have died, will be interviewed for lifetime occupation, residence, and smoking histories.

EPIDEMIOLOGIC STUDIES OF CANCER IN LOUISIANA

W.J. Blot, Tulane University of Louisiana, School of Medicine, *1430 Tulane Ave., New Orleans, Louisiana* 70112

Mortality from lung, bladder, and pancreatic cancers has been shown to be excessive in Louisiana's southern parishes. This study was designed to generate clues to the causes of these cancers through a comparison of cancer and matched non-cancer death certificates with respect to residence location, occupation/industry classification, and ethnic classification of family surname. Death certificates of residents of 19 parishes were abstracted for the years 1960 to 1975. Parishes to be included were selected for their high lung, bladder, or pancreas mortality rates, or their heavy concentrations of petroleum, chemical, or paper manufacturing industries.

2.0734,

BLADDER CANCER IN NEW HAMPSHIRE, VERMONT, AND MAINE

R. Hoover, Westat Inc., *11600 Nebel St., Rockville, Maryland* 20852 (PROJECT #11)

New Hampshire, Vermont, and Maine have high rates of bladder cancer for both males and females. Since bladder cancer is usually more common in males than females, conducting a study in these three states provides an unusual opportunity to study bladder cancer in both sexes.

The study will be restricted to those areas within the three states which have high rates of bladder cancer for either males or females. The study will include a next-of-kin survey for all deaths due to bladder cancer in the past five years in those counties and a newly diagnosed case survey covering a period of twenty-four months. One control will also be selected for each case in both the next-of-kin survey and the new incidence survey. In addition to the surveys, a library study to characterize industrial and other relevant features of the study areas will be performed, as will be a collection of air and water quality samples. The study will be patterned on the Special Study of the Role of Saccharin in Bladder Cancer.

The primary objective of the study is to assess whether there is an association between certain environmental exposures and the high rates of bladder cancer in New Hampshire, Vermont, and Maine. In addition, the study will help to refine the understanding of associations that are already known to exist. The exposures being investigated are: 1) Consumption of artificial sweeteners 2) use of tobacco products, 3) occupational exposures, 4) residential history (for source of drinking water and air quality), 5) consumption of coffee and other beverages, 6) certain illnesses and medical therapies, 7) use of hair dyes. Of particular interest among these exposures are occupational exposures and air and water quality. In order to provide additional data to help analyze any associations, a historical study of industry in the data will be done and air and water quality samples will be taken in certain areas.

INVESTIGATION OF POSSIBLE CORRELATIONS BETWEEN MORPHOLOGICAL AND EPIDEMIOLOGICAL CHARACTERISTICS OF BREAST CANCER

B. Stenkvist, University Hospital, Dept. of Clinical Cytology, *75014 Uppsala, Sweden* (CB-53854-S)

To ascertain possible correlations between the morphologic variables and the established epidemiological risk factors of breast cancer. The results may be applied not only to identify individuals at high risk of breast cancer but may be used prognostically to predict course of disease. This prospective study will consist of two phases: Phase I will consist of a pilot study of histopathologic material from 110 breast cancers from four counties in Sweden utilizing the computerized Central Swedish Cancer Registry. The tumors will be classified histologically according to WHO (Scarff and Torloni 1968) and Acherman's Classification (1970). Another aim of this project is to make a quantitative evaluation of a number of morphological characteristics by computer analysis of tumor cell populations utilizing a Leitz MPVII scanning photometer connected to a PDP-8 computer with 24K of core, and relate these to the standard classification. Planning for the epidemiologic data will be collected on each patient and computerized. Under Phase II statistical analysis of the data will be made with application of the newly acquired morphologic classification to the epidemiologic variables.

EPIDEMIOLOGIC STUDIES OF LUNG CANCER

R.C. Herrenkohl, Lehigh University, Center for Social Research, *10 W. 4th St., Bethlehem, Pennsylvania* 18015

The overall objective of this study is to identify the risk factors for lung cancer in three counties of eastern Pennsylvania which are in the vicinity of a nonferrous zinc smelter. This is being accomplished through personal interviews of the next-of-kin of 447 persons who died of lung cancer (cases) during the years 1974-1977, and of 447 persons who died of other causes (controls) during the same period. Controls include other cancers and non-cancers, but exclude lung-related diseases. This epidemiologic investigation is designed to assess the roles of occupation, residence, environment, tobacco consumption, and diet in relation to lung cancer mortality in these counties.

INCIDENCE OF CANCER AS RELATED TO INDUSTRIAL EMISSION IN CONTRA COSTA COUNTY, CALIFORNIA

W. Blot, State Dept. of Health, *2151 Berkeley Way, Berkeley, California* 94704 (PROJECT #8)

Cancer incidence data (both mortality and morbidity) are available for Contra Costa County by census tract, age, sex, race, and other demographic characteristics related to cancer type and site from the California Tumor Registry (CTR) for years 1969-74, from the third National Cancer Survey, and from hospital records and death certificates for years 1974-76. The county contains over 500,000 people. There is clustering of manufacturing activity along the waterfront, including petroleum and chemical plants among the more than 7,000 industrial units which account for approximately 70% of the 30,000 tons shipped through the Golden Gate each year. The California Health Department is interested in, and concerned about, the emission of these toxic substances, and in cooperation with EPA, has planned an epidemiologic program to further evaluate and control this source of pollution.

A CASE-CONTROL STUDY OF ENVIRONMENTAL DETERMINANTS OF LUNG, PANCREAS, AND STOMACH CANCER IN SOUTHERN LOUISIANA

L.W. Pickle, Louisiana State University, Medical Center, School of Medicine, *1542 Tulane Ave., New Orleans, Louisiana* 70112

Mortality rates for lung, pancreas, and stomach cancer have been shown to be exceptionally high in a number of southern Louisiana parishes. The current study is an investigation into the reasons for these excesses. Cancer cases and matched controls (or their next-of-kin) diagnosed at selected area hospitals will be interviewed and their lifetime histories of smoking, occupation, residence, and diet compared. Relative risk estimates will be obtained to quantify the influence of occupational, residential, and ethnic factors on the occurrence of these cancers. It may also be possible to correlate these high cancer rates to environmental measurements data to be collected by the EPA in this area.

MORBIDITY AND INDUSTRIAL HYGIENE STUDY OF FIBROUS MINERAL WORKERS (TALC)

T. Cameron, U.S. Dept. of Health & Human Services, Public Health Service, Center for Disease Control, National Inst. for Occupational Safety & Health, *4676 Columbia Pkwy., Cincinnati, Ohio* 45226

A cross-sectional study of 125 mine and mill workers in New York State, who were exposed to talc containing tremolite and anthophyllite, has shown an excess of pleural thickening related to exposure. The workers were given blood tests, chest x-rays, spirometry studies, and respiratory questionnaires.

A cross-sectional medical and industrial hygiene study of talc workers in other states is in progress. This includes 183 workers exposed to Montana talc, 71 workers exposed to Texas talc, and 52 workers exposed to North Carolina talc. The studies are of two types: cross-sectional prevalence study, and a short-term study of acute pulmonary function changes in some of the workers from the prevalence study.

The prevalence study will examine the association of medical findings with cumulative exposure and respirable particles.

The acute changes in pulmonary function were measured by: 1) chest x-rays; 2) spirometry studies (before and after shift in some workers); 3) diffusion studies in workers older than 35 years of age; 4) sputum tests on workers older than 35 years of age; 5) respiratory questionnaires with respiratory symptoms, smoking, and occupational history information; and 6) personal and area environmental sampling.

CANCER MORTALITY STUDIES

L.M. Schuman, University of Minnesota, Minneapolis Campus, School of Public Health, Dept. of Epidemiology, *1325 Mayo Memorial, Minneapolis, Minnesota* 55455

Maintain basic mortality follow-up of the Lutheran Brotherhood cohort. Augment data base to include all information on 'lapses', i.e., include date policyholder lapsed, date of death (cause of death), or follow-up on survival (date last known to be alive). This is to be done for all previous lapses as well as for future lapses. Provide final reports (manuscripts) for NCI use on three studies already begun in 1978. Provide NCI with computer tapes of data base files, including follow-up and 'lapses' information. Descriptions of the files and identification of all data elements should also be included. Analytical or extract tapes should be submitted separately, with appropriate narratives to describe contents. These tapes

should be provided quarterly or semiannually, depending on the amount of update required.

INDUSTRIAL EMISSION IN NEW JERSEY AND ITS RELATIONSHIP TO CANCER
T.J. Mason, State Dept. of Health, *135 W. Hanover St., Trenton, New Jersey* 08618 (PROJECT #9)
The NCI has a contract with the New Jersey Department of Health to investigate bladder cancer. This ongoing investigation has identified specific places in New Jersey where bladder cancer rates are elevated, and are continuing to increase. The EPA has developed expertise in taking environmental samples (e.g., air, water, soil, etc.) and analyzing them for known or suspected carcinogens. The NCI will inform the EPA concerning the specific places in New Jersey where environmental sampling needs to be done. The EPA will collect samples, and provide these data to the NCI.

2.0770,
VIRAL KERATOCONJUNCTIVITIS AND RELATED DISORDERS
E. Jawetz, University of California, San Francisco Campus, School of Medicine, Dept. of Microbiology & Immunology, *551 Parnassus Ave., San Francisco, California* 94122 (R01 EY 00186-26)
We propose to continue our productive studies on external eye diseases caused by chlamydial and viral agents, and etiologically and epidemiologically related infections. We plan broad, multidisciplinary investigations pertaining to diagnosis, immunology, treatment and control of infectious eye diseases which are important causes of human blindness. We shall concentrate particularly on chlamydial eye infections caused by different immunotypes of chlamydiae of genital or ocular origin on herpetic keratoconjunctivitis and on systemic aspects of herpesvirus infections, originating in the genital tract or in the eye, on adenovirus ocular infections, and on infections of as yet undefined etiology. We shall continue to study biologic and immunologic features of etiologic agents, the clinical and immunologic aspects of host responses in man, the dynamics of drug treatment (including controlled treatment trials), and epidemiologic features which determine behavior of the infections in various geographic and social environments. We bring to these studies specialized skills in ophthalmology, microbiology, virology, immunology, epidemiology, and chemotherapy as represented by various members of our group. We hope to contribute materially in the future, as we have in the past, to improved understanding of host-parasite relationships and mechanisms of control of a number of serious external eye diseases.

2.0771,
OCULAR ZOONOSES - THE CHLAMYDIAL INFECTIONS
H.B. Ostler, University of California, San Francisco Campus, School of Medicine, Dept. of Ophthalmology, *551 Parnassus Ave., San Francisco, California* 94122 (R01 EY 01205-03)
By the use of various culture techniques and serologic methods we propose to determine the frequency of latent chlamydial infections in commonly used laboratory and domestic animals. Suitable animal models will be developed to study the pathophysiology of chlamydial infections and to investigate potentially useful drugs for the treatment of chlamydial infections in man.
Sporadic human endemics, thought to arise from man's contact with various mammalian or avian species, will be investigated for chlamydial etiology. Various culture techniques and serologic methods will be applied, and the epidemiology of the ocular disease will be studied in detail.

2.0772,
ACUTE HEMORRHAGIC CONJUNCTIVITIS AND INTERFERON
G.J. Stanton, University of Texas, Medical Branch at Galveston, School of Medicine, Dept. of Microbiology, *300 University Blvd., Galveston, Texas* 77550 (R01 EY 01715-04)
Based on studies that show (1) enterovirus 70 (E70) and Coxsackievirus A24 (CA24) can be grown in primary conjunctival cells of mice, rabbits, and/or monkeys and that E70 virus is replicating in rabbits, the following research program is proposed: (a) to attempt to infect the eyes and central nervous system of immature species of mice, rabbits, hamsters, and monkeys with virus isolates that grow well in cell or organ cultures of each particular species and to concentrate on determining the site and extensiveness of E70 replication in rabbits. (b) As suitable animal model systems are established, the effect of IF, IF inducers specific hyperimmune antibody, and temperature elevation on pathogenesis of this eye disease will be studied and explored in detail to determine optimal conditions for possible application of these defense factors for control of epidemics or individual cases of the disease. (c) To continue to determine from human specimens, including tears, eye scrapings, and acute and convalescent serum (a larger number of these specimens are present in the laboratory and more are expected) the relationships between antibody formaton virus replication and the pathogenesis of this infection in man. We expect to obtain more samples from patients, especially for those infected with E70. (d) To physically and biologically characterize and attempt to further clarify the role of the early appearing antiviral activity in tears on the pathogenesis of acute hemorrhagic conjunctivitis. (e) To continue the serum survey and to characterize the nature of the anti-E70 substance present in 90 percent of the serum samples. The presence of this substance complicates any serologic survey and could be a diagnostic problem during outbreaks when definitive diagnosis has to be accomplished serologically. It would be desirable to be able to easily eliminate this substance, if it is not antibody, prior to testing for specific antibody. (f) To explore in detail the synergistic antiviral effect of antibodies and interferon both in cell cultures and animal model systems.

HLA AND GENETIC STUDIES IN DIABETIC RETINOPATHY
R.C. Ramsay, University of Minnesota, Minneapolis Campus, School of Medicine, Dept. of Ophthalmology, *1305 Mayo, Minneapolis, Minnesota* 55455 (R01 EY 02455-02)
The natural history of diabetic retinopathy is extremely variable among individual diabetic patients. At the present time no method is available that is able to predict which diabetics will develop the more advanced forms of retinopathy with their attendant poor visual prognosis. There is evidence that genetic factors, in addition to the metabolic abnormalities of diabetes, are important in the pathogenesis of diabetic retinopathy. The hypothesis for the proposed study is that there are one or more 'microangiopathy genes' in linkage disequalibrium with the HLA genes which determine susceptibility to serve diabetic microangiopathy. We plan to test this hypothesis by studying HLA A,B,C and D antigens and B-cell alloantigens in JIDD patients with and without severe retinopathy to see if differences exist. Similar studies will be carried out in AOD patients with and without advanced retinopathy. Prospective studies will be completed in patients followed in the DRS and ETDRS at the University of Minnesota. In addition to these association studies, linkage studies will be carried out in large diabetic multiplex families selected for either a high or low prevalence of proliferative retinopathy.
The determination of genetic markers for microangiopathy, which could serve as predictors for vascular complications, would have great practical significance for all patients with diabetes mellitus.

CASE CONTROL STUDY OF DIABETIC RETINOPATHY
L.I. Rand, Joslin Diabetes Foundation Inc., *170 Pilgrim Rd., Boston, Massachusetts* 02215 (R01 EY 02636-02)
A Case-Control Study of diabetic retinopathy is underway comparing age and duration matched long term insulin dependent diabetics with and without retinopathy in regard to certain demographic, ocular, systemic, and metabolic factors to see if a profile for the high risk of retinopathy patient can be developed. Patients with little or no retinopathy will be followed prospectively to assess the predictive value of the factors identified.
A detailed manual of procedures (MOP) has been developed, forms and procedures tested, and patient recruitment has begun. We hope to follow-up on several cohorts of patients previously seen at the Joslin as part of the screening for case control patients.
Among the factors being studied will be diabetic onset symptoms, blood sugar levels, cigarette smoking, Hemoglobin A1C, growth hormone and glucagon after arginine stimulation, sedimentation rate, lipid profile including HDL cholesterol, 2'3 DPG, platelet aggregation, platelet growth factor, intraocular pressure, refractive error, lens autofluorescence. Vitreous fluorophotometry and mean retinal circulation time measurements using computer densitometric reading of fluorescein angiograms will be done on selected patients.

EPIDEMIOLOGICAL STUDY OF DIABETIC RETINOPATHY
R. Klein, University of Wisconsin, Madison Campus, Medical School, Dept. of Ophthalmology, *307 N. Charles St., Madison, Wisconsin* 53706 (R01 EY 03083-01)
A study of the prevalence and severity of diabetic retinopathy will be conducted in a group of 2,400 diabetic patients in their home communities. Objective recording of retinopathy by use of stereoscopic fundus photography combined with a standardized protocol for grading the retinopathy will be used. Grading of the stereo photographs will provide a sensitive and reproducible method for detection of retinopathy. The frequency and causes of visual impairment will be determined. The prevalence of retinopathy and of its various component lesions will be evaluated with respect to duration and age at diagnosis of diabetes, blood pressure level and smoking history.

PSYCHOSOMATIC PREDICTORS OF HEART DISEASE IN ADOLESCENCE

C.J. Leitch, University of Washington, School of Nursing, Dept. of Community Health Care Systems, *Seattle, Washington* 98105 (R01 HL 22378-02)

The overall objective of the proposed research is to explore the variance and interrelatedness of selected psychosocial and somatic variables between a group of hypertensive and normotensive adolescents with the specific aim of developing a typology for identifying coronary proneness in youth. One hundred hypertensive student subjects and one hundred matched controls, ages 12-20, have been given physical examinations and psychologic tests by physicians and nurse practitioners at the Adolescent Clinic, Tacoma-Pierce County, Washington Health Dept. Data generated by the study will be blood pressure level, cholesterol, triglycerides and HDL levels, physical findings on examinations, salt abuse, physical activity, obesity and relative weight, family health and social history, needs achievement score, school anxiety scores, environmental change scores and scores on an interview designed to identify Type A behavior in adolescents. Data will be analyzed in terms of differences, variance, relatedness and clustering of factors. Since indications are that chronic CHD may have its genesis in childhood, this study has epidemiological significance especially to school nurses who could design programs to reverse the prognostic indications of possible findings during youth when unhealthful practices are easier to modify. It is planned that this study will lead to demonstration projects and long-term follow-up studies employing a variety of methodologies to test the reversal of significant findings.

THE ETIOLOGY/PREVALENCE OF PERIPHERAL ARTERIAL DISEASE

M.H. Criqui, University of California, San Diego Campus, School of Medicine, Dept. of Community Medicine, *P.O. Box 109, La Jolla, California* 92093 (R01 HL 22255-02)

The objective of this study is to determine the prevalence of peripheral arterial disease (PAD) in a defined population by non-invasive techniques, to investigate the etiology of peripheral arterial disease by evaluating the association of certain cardiovascular disease risk factors with PAD, and to evaluate the degree of correlation between PAD and coronary heart disease (CHD) on a polulation basis in order to determine whether non-invasive tests of PAD can be used as a marker for CHD.

PAD is measured using four tests: (1) Flow velocity by Doppler ultrasound, (2) Segmental blood pressure, (3) Post-occlusive reactive hyperemia, and (4) Pulse reappearance time. Factors being investigated with regard to PAD include blood pressure, lipids, lipoproteins including the cholesterol/triglyceride ratio in VLDL, fasting plasma glucose, glycosylated hemoglobin, apoprotein E, a medical history, diet, medications, alcohol use, and cigarette smoking. Information on subsequent cause-specific mortality in this population will be obtained.

ATHEROSCLEROTIC DISEASE AND RISK FACTORS IN TWINS

G.D. Friedman, Kaiser Foundation Research Inst., *1956 Webster St., Room 310 B, Oakland, California* 94612 (R01 HL 21971-03)

Using the large Kaiser-Permanente Twin Registry, we are carrying out a three-phase study of atherosclerotic disease and risk factors in adult like-sex monozygotic and dizygotic twins. The main objectives are to assess the degree of genetic determination of atherosclerotic disease, particularly coronary heart disease (CHD) and its risk factors, and to assess the role of environmental factors in CHD, with emphasis on cigarette smoking and alcohol consumption. The first phase is an analysis of responses to a questionnaire on health status, habits, and environmental exposures. The second is a review and analysis of medical records of those twins who are Kaiser Foundation Health Plan subscribers. The third phase will be a medical examination of 432 pairs of female twins including extensive laboratory tests. Long-term follow-up of participants is also planned.

HEMODYNAMIC EFFECTS OF DIETARY SODIUM IN MAN

J.M. Sullivan, University of Tennessee, Center for the Health Sciences, School of Medicine, Dept. of Medicine, *62 S. Dunlap St., Memphis, Tennessee* 38103 (R01 HL 21523-02)

Compelling evidence links dietary sodium intake with the prevalence of hypertension in several human population groups around the world. Epidemiologic studies of man and selective inbreeding studies in rats suggest that most population groups contain individuals who are either salt-sensitive, salt-resistant, or who lie somewhere in between. Limited, short-term human studies suggest that the hemodynamic basis of these differences lies in sodium's property of decreasing vascular resistance in normal subjects while increasing resistance in hypertensive subjects. Additional studies are needed to verify this important point and to determine its long-term significance. Non-invasive methods of estimating changes in total peripheral vascular resistance in response to dietary sodium manipulation using echocardiography and venous occlusion plethysmography will be tested as a means of identifying salt-sensitive individuals in the population who might benefit from preventive dietary measures. These methods have the advantage of avoiding the anxiety-provoked sympathetic nervous system stimulation associated with the placement of right heart catheter or intra-aeterial cannulae. The relative effect of dietary potassium on peripheral vascular resistance will also be studied. The groups to be studied will include normal subjects, normotensive subjects with a family history of hypertension, subjects with labile essential hypertension and subjects with mild, fixed essential hypertension. The relationships of dietary sodium and potassium with urinary prostaglandin excretion in the various groups of patients will also be explored.

NATURAL HISTORY OF ASTHMA-METHACHOLINE TOLERANCE TEST

R.G. Townley, Creighton University, School of Medicine, Dept. of Medicine, *629 N. 27th St., Omaha, Nebraska* 68131 (R01 HL 21494-01A1)

We are interested in the factors responsible for the exquisite bronchial sensitivity of patients with bronchial asthma to certain mediators. This is a continuation of a population, genetic family study of certain host factors in bronchial asthma. This study deals with factors that are involved in determining the natural history of bronchial asthma in the general population. One of the major questions in this study is

whether the bronchial sensitivity of asthmatic individuals to methacholine occurs at an early age even before clinical manifestation of the disease occurs. We intend to use the methacholine inhalation challenge test as a means of defining asthma and possibly using this as a marker for elucidation of its genetic characteristics. Another major part of this study is to determine whether asthma is acquired, genetically transmitted, and/or the result of interaction of environmental and host factors.

We intend to study the natural history of asthma and methacholine sensitivity in patients who currently have asthma, former asthmatics, their atopic and non-atopic siblings, concordant and discordant twin pairs and in persons in asthmatic families with alpha-1-antitrypsin phenotypes MS, MZ and MM. We will study the genetic characteristics of predisposition to asthma, in the above high risk groups as well as low risk groups such as non-atopic families. Parameters to be assessed include methacholine tolerance, allergy history and skin tests, serum IgE, protease inhibitor (Pi) types, and Histocompatability antigens.

COMMUNITY STUDIES OF OBSTRUCTIVE LUNG DISEASE

G.J. Beck, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (R01 HL 21352-03)

We have performed cross-sectional surveys on the prevalence of symptoms of obstructive lung disease and on lung function in about 7000 residents aged 7 years and older of one urban and two rural communities, in Connecticut and in South Carolina. The results provide data on normal lung function in relation to age, sex, race and smoking habits, as well as comparison of symptom prevalence and of lung function in urban vs. rural residents and in black vs. white children and adults. We plan to use this extensive data base in longitudinal studies of lung function increase and incidence of asthma and of respiratory symptoms in children and adolescents, and of lung function decrements with age in adults, as a function of smoking habits, residence and occupation. There is emphasis on the study of women, adolescents and blacks, about whom few such data are available. The results will be related to data on outdoor and indoor air pollution, to evaluate the significance of these as risk factors in obstructive lung disease.

VASCULAR LESIONS OF DIABETES IN OKLAHOMA INDIANS

K.M. West, University of Oklahoma, Health Science Center, College of Health, Dept. of Biostatistics & Epidemiology, *Box 26901, Oklahoma City, Oklahoma* 73190 (R01 HL 21039-03)

As part of a multinational cooperative research program sponsored by the World Health Organization, vascular manifestations of diabetes will be studied in a large population of Oklahoma Indians. Despite their great importance and their resistance to present therapeutic and preventive measures, both the microvascular and macrovascular lesions are still poorly understood. Recent evidence indicates, however, that there are major differences among populations in susceptibility to these lesions. Determination of the magnitude and character if these differences, and study of the genetic, racial, and environmental factors to which they relate, may be expected to yield useful information and clues applicable to their cause and mitigation. Previous comparative data have been difficult to interpret because methods have not been adequately standardized or detailed, and groups studied have very seldom been representative or large. Circumstances in Oklahoma are uniquely propitious because: 1. A large and virtually complete universe of Indian diabetics in a single circumscribed geographic area can be studied to determine and evaluate factors responsible for both intergroup variations in susceptibility to these lesions (coronary, retinae, kidney, brain, and legs). 2. Because data will be collected using standadized methods, they can then be compared directly with data from several other populations (WHO study) in which racial, genetic, cultural, social, nutritional and environmental circumstances vary widely. 3. Some of our results and the characteristics of our sub-populations can also be related to previously published data in other groups including other Indian diabetic populations in wich rates of certain vascular manifestations have been either high or low. 4. The design will also permit comparison and study of these lesions in several Oklahoma tribes and groups of tribes from widely divergent origins including two of the largest tribal groups in America (Plains Indians and Five Tribes Indians).

GLYCEMIA, OTHER TRAITS AND CV DEATH IN 40,000 PERSONS

J. Stamler, Northwestern University, Chicago Campus, School of Medicine, Dept. of Preventive Medicine & Community Health, *303 E. Chicago Ave., Chicago, Illinois* 60611 (R01 HL 21010-03)

A 'second generation' prospective epidemiologic study on atherosclerotic cardiovascular diseases, particularly coronary heart disease, is under way to elucidate the role of glucose intolerance as an independent risk factor for macrovascular disease. It also has the goal of clarifying the role of other traits (e.g., hyperuricemia, obesity, rapid resting heart rate, pure systolic hypertension, ECG abnormalities) as risk factors, independent of the major risk factors (hypercholesterolemia, hypertension, cigarette smoking) demonstrated by the 'first generation' U.S. longitudinal epidemiologic studies. Almost 40,000 white and black men and women, chiefly 25-64 and identified in the Chicago Heart Association Project in Industry from 1967 to 1973 are to be followed for 10 years to determine the relationship of glucose tolerance (as well as clinically diagnosed diabetes, untreated and treated) and each of the other traits to rates of mortality from All Causes, Cardiovascular Diseases, Coronary Heart Disease, etc. For example, the contribution of glucose intolerance and clinical diabetes to risk of death, both cause-specific and all causes, is to be assessed with the following other baseline factors controlled in bivariate and multivariate analyses; age, serum cholesterol, blood pressure, cigarette smoking, relative weight, serum uric acid, heart rate, ECG abnormalities, and such demographic variables as education and marital status. For about 4,500 persons screened twice, the significance of two values and of changes in these variables for predicting risk is to be assessed. For 4,108 persons, the interplay between glucose tolerance and scores from the Jenkins Activity Survey (as well as other cited factors) in influencing risk of macrovascular disease death is to be evaluated.

CHRONIC OBSTRUCTIVE PULMONARY DISEASE--FAMILIAL/GENETIC

R.D. Miller, Mayo Foundation, *200 1st St. S.W., Rochester, Minnesota* 55901 (R01 HL 20875-03)

The increasingly common problem of COPD has been related to numerous extrinsic factors. Relatively little is known about host factors. Low alpha 1 antitrypsin levels explain only a small portion of cases. Recent demonstration of variation in leukocyte elastase activity among individuals suggests that protease/antiprotease relationship may be an important host mechanism. We recently studied 111 index subjects with COPD and 111 controls with demonstrated normal pulmonary function matched for age cohort, sex, smoking history, and occupation. With these predisposing factors matched, other host factors were analyzed: genetic, immunologic, and endocrine characteristics. Among the serum immunoglobulins, IgD was significantly higher in index cases as were IgD and IgM immunoglobulins in nasal secretions. Serum components of complement C3 and C4 were significantly lower in index cases than controls. Recent studies have shown that leukocyte elastase consumes complement, reducing serum levels. Predisposition to COPD has been shown in homozygote deficient alpha 1 antitrypsin cases. Since alpha antitrypsin specifically neutralizes leukocyte elastase and homozygote deficient cases are uncommon (3 ZZ's in our index group) in proportion to the total number of cases of COPD, high levels of leukocyte elastase could be a predisposing factor in subjects with more normal levels of alpha 1 antitrypsin. Since our subjects showed lower complement than controls, this finding reflects high leukocyte elastase activity. We propose to study leukocyte elastase and protease/antiprotease complexes in our index subjects, matched controls, and closest sibling of the same sex of index and control subjects whom we have already studied. We would plan to measure the pulmonary function to determine the three year decrement in values and compare these to the leukocyte elastase values and to other risk factors we have reported. The decrement in function may be a more sensitive measure of the pathogenesis of disease than a cross sectional study of these groups.

PHYSICAL ACTIVITY AND INCIDENCE OF CHRONIC HEART DISEASE

H.L. Taylor, University of Minnesota, Minneapolis Campus, School of Public Health, *1325 Mayo Memorial, Minneapolis, Minnesota* 55455 (R01 HL 20662-02S1)

The evidence about physical activity and/or physical fitness as risk characteristics for coronary heart disease (CHD) is fraught with inadequacies in the design of studies and the information collected. These inadequacies may explain contradictory findings reported. In one study of physical activity and/or physical fitness, the United States Railroad Study (USSR), a unique combination is available of complete CHD risk factor ascertainment, estimates of leisure time and occupational physical activity, and an objective measure of physical fitness (a standardized exercise test). The USSR is a prospective study of 2571 men initially aged 40-59 employed by 20 railroad companies operating in the northwestern United States. Nearly 70% of a sample of all executives, dispatchers, switchmen, and clerks employed by these companies in 1957 was examined, first between 1957-1960, and again between 1962-1965. The USSR is a component of the International Cooperative Study of Cardiovascular Epidemiology (Seven Countries Study). Complete mortality followup has been accomplished through 10 years post-enrollment with data from the Railroad Retirement Board. It is proposed to study, in year 2 of this project, the relationships among CHD risk factors, physical activity, physical fitness, and mortality due to CHD. Such analysis will be made possible during year 1 of the project. Not only is this information needed to elucidate the nature and degree of any role of physical activity and fitness in CHD, but the study is timely in this period when professional public awarness is increasing of CHD risk factors and the potential for prevention of CHD.

BLOOD GLUCOSE HGB A1C, AND DIABETIC VASCULAR DISEASE

K.H. Gabbay, Childrens Hospital Medical Center, *300 Longwood Ave., Boston, Massachusetts* 02115 (R01 HL 20539-03S1)

We are currently conducting a perspective evaluation of the role of diabetic blood glucose control in the development of microvascular disease and accelerated macrovascular disease in juvenile onset diabetic patients. Diabetic control is being evaluated by

serial measurements of glycosylated hemoglobins (Hgb A1 abc) at two month intervals, which provide an accurate integrated index of blood glucose levels over an extended period of time. Microvascular disease is assessed by the rate of progrssion of quadriceps capillary basement membrane thickness (CBMT) obtained on muscle biopsies at the beginning of the study, two and four years later. The traditional risk factors for the development of macrovascular disease in this population are being measured and correlated with the various parameters of diabetic control.

This proposal will analyze platelet function in this well characterized group of juvenile onset diabetics. The study will determine the nature and presence of platelet function abnormalities to the other parameters being measured in this population (i.e. glycosylated hemoglobin, capillary basement membrane thickness, plasma lipids, etc.). We will seek to determine the relationship of various parameters of diabetic blood glucose control to these platelet abnormalities, and more specifically analyze the role of the prostaglandin endoperoxide production pathway in the abnormal platelet function noted in these patients.

In addition, this proposal seeks to strengthen the existing data management system developed for this study by providing additional personnel to facilitate data entry and analysis.

MYOCARDIAL FUNCTION RISK FACTORS, AND FUTURE CHD

W.K. Harrison, University of California, San Diego Campus, School of Medicine, Dept. of Anesthesiology, *P.O. Box 109, La Jolla, California* 92093 (R01 HL 20574-04)

Ultra low frequency ballistocardiograms (Bcg) and transcutaneous carotid artery pulse recordings (CP) are being made on patients of the Multiple Risk Factor Intervention Trial (MRFIT). Three clinical centers of MRFIT with 2000 patients and the Coordinating Center are involved in this ancillary study. Bcg a and CP are recorded on magnetic tape cassettes in standarized format controlled by a data encoder developed by the applicant. Cassettes are then mailed to the applicant's laboratory for analysis by digital computer. Analog recordings on the cassettes are converted to digital time series on industry compatable nine tract digital magnetic tape. This step is carried out on a specialized digital tape recorder. Data from these first pass digital tapes are then edited to produce second pass archive tapes with ideal properties for further processing. The editing procedure is accomplished on large scale computers of the main institutional computer center. Digital time series of Bcg and CP are then analyzed by a feature recognition and measurement (FRAM) program in the same machine. Standardized objective measurements of Bcg and CP obtained in this way are then employed in crossectional analyses and multivariate prognostic calculations. Bcg and CP are expected to demonstrate response to interventions and add important independent contributions to known predictive power of established risk factors for coronary heart disease.

PROSPECTIVE BUNDLE BRANCH BLOCK STUDY

M.M. Scheinman, University of California, San Francisco Campus, School of Medicine, Dept. of Medicine, *551 Parnassus Ave., San Francisco, California* 94122 (R01 HL 20238-03)

The objective of the proposed research is to correlate measurements of atrioventricular node (A-H) and infranodal (H-Q) conduction times and refractory periods with the total mortality, incidence of sudden death and progression to higher grades of AV block in patients with bundle branch block (BBB). His bundle recordings will be obtained in patients with bundle branch agreeing to enter this study in order to estimate AV nodal and infranodal conduction time. These patients will be followed either in the cardiac clinic at San Francisco General Hospital or by private referring physicians. Either the patient or referring physician is contacted at 3 month intervals and pertinent physical findings, symptoms and 12-lead EKG are recorded. A 24-hour continuous EKG monitor is obtained at least 3x/year and more often when clinically indicated. In the event of death, a Public Health nurse interviews the patient's family or friends, reviews the death certificate or results of the post-mortem examination (where available) in order to determine the cause and suddenness of the demise. Documented episodes of 2 degrees and 3 degrees AV block will be compiled. The projected study represents a continuation of an ongoing study funded by the Bay Area Research Committee and institutional grants. Analyses of the data will hopefully allow us to define a subset of patients with BBB who are at increased risk for development of either sudden death and/or high grade AV block and may have important implications with regard to prophylactic cardiac pacemaker implantation in patients with BBB.

GENETIC EPIDEMIOLOGY OF PRECURSORS OF HYPERTENSION

R.H. Ward, University of Washington, School of Arts & Sciences, Dept. of Epidemiology, *Seattle, Washington* 98105 (R01 HL 20159-04)

This project aims to specify the role played by those genetic, environmental, and psychosocial factors causing blood pressure to rise in a migrant population.

The Tokelauans are a Polynesian people migrating from their traditional atolls to New Zealand where by analog with other migrating Polynesians, a rise in blood pressure is expected to follow migration. Approximately one half of the population has remained in its traditional setting while the other half has migrated to New Zealand. The extensive data already collected on this population includes detailed genealogical records; a wide range of medical, sociological and physiological variables for the pre-migrant period and which is updated every 2-3 years in both the migrant and non-migrant populations; anthropometric and genetic marker data for a sub-sample of the population.

By use of regression models based on the distribution of genetic relationships between individuals in similar and different environments we will attempt to estimate the influence of the genetic component and the genotype-environment interaction component on the distribution of blood pressures and related physiological variables. Particular attention will be directed to the factors influencing blood pressure in the migrant children and towards the construction of a pre-clinical 'at-risk' profile for this population.

CORONARY RISK FACTORS IN CHILDREN

R.M. Lauer, University of Iowa, School of Medicine, Dept. of Pediatrics, *Jessup Hall, Iowa City, Iowa* 52240 (R01 HL 20124-03)

This epidemiologic study is a multidisciplinary approach to ellucidate the relationship of early childhood levels of blood lipoproteins, blood pressure and anthropometric measures to the development of hyperlipidemia and hypertension in late childhood and early adult life. An entire school district of approximately 6,000 school age children in Muscatine, Iowa have had their plasma lipids, blood pressure, heights, weights, and triceps skinfold thickness measured on three occasions over a five year period. Thus, the entire distribution of these variables are known at each school age level, and the relationship of the measurements made on the same individual on repeated occasions can be estimated.

It is planned to examine the familial and psychologic factors relating to the distribution of blood pressure, and to study cardiac output and vascular resistance not only as they exist across the distribution of blood pressure but also as they are affected by orthostatic stress and sodium intake.

FACTORS IN BLOOD PRESSURE LEVELS OF CHILDREN

G.E. Fraser, Loma Linda University, School of Health, Dept. of Biostatistics & Epidemiology, *Loma Linda, California* 92354 (R01 HL 20005-04)

This study aims to determine the relationship of dietary habits, psychosocial factors and physical fitness to the BP levels of children. It is difficult to study diet in relation to blood pressure levels in the USA because of the uniformity of US dietary practices. Seventh-Day Adventists (SDAs) are a conservative religious group, many of whom adhere to unique dietary practices such as the avoidance of meat and caffeine and their exposure to, and mechanisms of coping with, stress may be considerably different from the general population.

The study population consists of 1st-10th grade students attending SDA parochial schools as well as public schools. Approximately 9,000 students will initially be screened with 3 BP determinations. Detailed information on dietary habits, psychosocial factors and fitness levels as well as 9 BP measurements will then be obtained at school from all students in the extremes (1,200) of their respective age-sex distribution and a sample (600) of those with intermediate levels. Similar information, as well as BP measurements (x 3) will also be obtained from parents of this sample of students. Parent-child pairs which are markedly discordant or concordant on BP level will be studied in greater depth. We will also be able to observe whether changes in BP occur in a sample of SDA students who experience marked change in dietary habits and social environment by transferring to SDA boarding schools. The population will include adequate numbers of comparable persons of 3 ethnic groups (Blacks, Mexican-Americans, Whites) who range in dietary habits from spartan pure vegetarians to the extremes of the typical American diet. Psychosocial traits may also be widely discrepant in segments of this population. Thus this study holds great promise of identifying modifiable dietary or psychosocial factors related to elevated BP in both children and adults.

HIGH BLOOD PRESSURE IN THE YOUNG

J.M. Kotchen, University of Kentucky, School of Medicine, Dept. of Community Medicine, *Limestone & Euclid, Lexington, Kentucky* 40506 (R01 HL 19956-04)

The proposed research involves a 7-10 year follow-up of identified populations of young adults to determine factors in adolescence associated with subsequent hypertension. We propose to follow young mothers who, as adolescents, experienced hypertension during their first pregnancy and similar young mothers, normotensive during pregnancy. Recent follow-up studies at 3-6 years post partum indicate that women hypertensive during pregnancy and their children have higher blood pressures than controls; 14% of women hypertensive during pregnancy, but no control women, were found to have blood pressure greater than or equal to 140/90 on repeated measurements, and EKG studies showed evidence of increased left ventricular wall thickness. Group differences in renin-aldosterone responses to exercise were also found. We propose to follow these women and their children to determine whether hypertension of pregnancy is associated with subsequent hypertension and the emergence of hypertensive cardiovascular disease in young mothers, and higher blood pressures in their children compared to controls.

We also propose a follow-up of young adults who participated in a blood pressure screening project during high school in 1973. A five year follow-up in progress indicates that individuals in this population maintain their relative rank-order for blood pressure over time, and blood pressure measurements during adolescence are predictive of subsequent blood pressure. Relatively high blood pressures are associated with an increased prevalence of abnormal echocardiograms and exercise EKG studies. We propose to re-evaluate these individuals after 7-10 years to determine if relative blood pressure rank is maintained; to determine whether relatively high blood

pressure in adolescence predisposes to hypersion and hypertension of pregnancy; to study aggregation of cardiovascular disease risk factors in young adults; to identify early evidence of cardiovascular disease. Sympathetic nervous system activity, the renin-aldosterone axis, and steroid responses to graded ACTH infusions will be studied in 'pre-hypertensive' young adults to identify mechanisms that may be involved in the pathogenesis of hypertension. We will also study the effects of an exercise intervention program on high blood pressure in young adults.

A PROSPECTIVE STUDY - BLOOD PRESSURE IN NEWBORN TWINS

H. Gelband, University of Miami, School of Medicine, Dept. of Pediatrics, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152 (R01 HL 19930-04)

The primary research objective is to estimate the relative contributions of genetics and environment to blood pressure levels among a group of newborn twins. Blood pressure is measured on days 0, 1, 2, 3, 14 and 1, 3, 6, 9 and 12 months. Zygosity is determined through blood group analysis, dermatoglyphics, physical appearance, and placental assessment. Placentation is also analyzed for each twin pair with respect to intravascular communications. Additionally, parents and siblings of the twins are evaluated as to blood pressure, height and weight. The ultimate purpose of this research is to shed light on the etiology of blood pressure levels in order to aid in the identification of individuals most likely to experience elevated blood pressure.

HIGH BLOOD PRESSURE IN THE YOUNG, PREVALENCE & PRECURSOR

P.E. Baer, Baylor College of Medicine, School of Medicine, Dept. of Psychiatry, *1200 Moursund Ave., Houston, Texas* 77025 (R01 HL 19929-04)

This project is intended to explore blood pressure levels and responsivity of children, as well as their personality attributes, in relation to the presence of parental primary hypertension and parental personality attributes of a type that have been identified as related to primary hypertension. The intention is to examine separately and in combination the possible effect on children of parents' hypertension and personality. A principal question is whether one can identify child rearing attitudes and behaviors that suggest a mechanism for transmission between parents and children that produces elevated blood pressure in children. In addition, it is also important to determine whether parents train their children to become the kinds of persons that have psychological attributes that might later in life be associated with hypertension.

CHILDHOOD DETERMINANTS OF BLOOD PRESSURE

R.C. Ellison, Childrens Hospital Medical Center, *300 Longwood Ave., Boston, Massachusetts* 02115 (R01 HL 19922-03S1)

Data collected from the Boston cohort of the Collaborative Perinatal Study (over 8000 subjects studied between 1959 and 1973) are currently being evaluated in regards to blood pressure in the children. Determinants of blood pressure measured at seven years of age are being sought from the mother's blood pressure during pregnancy, a history of toxemia of pregnancy, a number of perinatal and early developmental factors in the child, and behavioral and socioeconomic factors during early life. Preliminary analyses have identified high blood pressure in the mother, prematurity, toxemia of pregnancy, low socioeconomic status and, especially, obesity in the child as factors related to higher blood pressure at seven years of age.

A subset of 400 of the original cohort (now 15 to 18 years of age) are being reevaluated at the present time. The resting blood pressure, as well as the blood pressure response to a number of stressful stimuli (cold pressor test, handgrip exercise, psychological stress), are being measured. The young subjects are also undergoing echocardiography to estimate left ventricular mass, contractility, and cardiac output, and are completing questionnaires designed to assess personality type, repressed hostility, and other such parameters.

HYPERTENSIVE PROGENY - PHYSICAL/HUMORAL PRECURSOR SEARCH

A.R. Hohn, Medical University of South Carolina, School of Medicine, Dept. of Pediatrics, *80 Barre St., Charleston, South Carolina* 29401 (R01 HL 19870-04)

PLAN: The proposed research will study children at high risk of hypertension because of hypertensive parents. Since blood pressure rises with age have been shown to begin during the childhood, this period may be ideal to study the genesis of hypertension. Changes of Physical (blood pressure) and Humoral (urinary kallikrein, prostaglandins, catecholamines and plasma renin) factors in response to exercise will be measured. A prospective four year study is planned in the form of a re-examination of both physical and humoral factors two years following the initial measurements.

PREVIOUS WORK: Results from preliminary studies at the Medical University have suggested the hypothesis that exercise stress testing of children may provide clues to identify risk factors, if not precursors, of adult hypertension because (1) such stress testing has shown a group of hyper-reactors in that their blood pressure responses were above the upper extreme of the distribution of 'normal' children. (2) Certain humoral factors, measured in Medical University of South Carolina research laboratories, seem to correlate with this finding.

POPULATION: Prospective study participants are available from those registered in the computer of the Family Practice Department at the Medical University of South Carolina. The population of this registry is shown to be similar to the population of Charleston County, South Carolina (an area with a high incidence of hypertension) as regards age, race, sex and income characteristics.

ANALYSIS: Case-control approaches are proposed to test the study hypothesis by estimating the odds of an effect, given selected characteristics such as vasoconstrictors (renin; catecholamines), vasodilators (prostaglandins; killikreins), obesity, cardiac output and family history. Control of confounding and interactive effects are planned in both categorical and continuous analyses. Further long-term prospective studies might be planned if 'tracking' seems apparent at the two year repeat evaluation.

ANTECEDENTS OF ADOLESCENT HYPERTENSION

S.H. Katz, Childrens Hospital of Philadelphia, Krogman Growth Center, *34th St. & Civic Ctr. Blvd., Philadelphia, Pennsylvania* 19104 (R01 HL 19869-04)

The objectve of this project is to study the epidemiology of elevated blood pressure and hypertension during adolescence. The study subjects are drawn from a population for which extensive longitudinal data, collected prospectively, are available. Three samples of adolescents are being studied: (1) a representative sample stratified by age, sex, and race; (2) a sample of adolescents who had elevated blood pressure at seven years of age; and (3) a sample of adolescents whose mothers had toxemia of pregnancy.

Antecedent variables include maternal and prenatal factors, complete postnatal medical histories, physical growth data, psychological test data, and detailed information about socioeconomic status.

Current assessments are taking place at three annual intervals and include the collection of demographic information, recent medical history, blood pressure measurements, growth and maturation measures (height, weight, skinfold thicknesses, and hand-wrist radiographs, and measures of steroid hormones), and psychological profiles.

Our analyses will aim to clarify the relationship among elevations in blood pressure, antecedent variables, and current parameters of physical growth, body composition, mental health status, socioeconomic status, and sexual maturation.

BLOOD PRESSURE OF CHILDREN AND YOUNG ADULTS

L.H. Kuller, University of Pittsburgh, Graduate School of Public Health, Dept. of Epidemiology, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (R01 HL 19864-03)

The project consists of two studies. The first study is a prospective investigation of blood pressure and heart rate in newborn infants with follow-up determinations conducted at 6, 15, and 24 months of age. The primary aims of the study are to establish the normal values of these variables in infancy, and to identify any possible racial difference in blood pressure and heart rate at this early age. The second portion of the project is an ongoing historical prospective study of the relationship between obesity, body type, social characteristics and casual blood pressure during adolescence and subsequent blood pressure levels in a predominantly white, middle-class population originally studied from 1957-1963.

ETIOLOGY OF SUDDEN DEATH IN ATHLETES

B.J. Maron, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Heart Lung & Blood Inst., Clinical Physiology Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 HL 01765-01 CB)

Sudden death occurring in competitive athletes is usually due to structural congenital cardiovascular disease. The most common cause of such deaths in this series was hypertrophic cardiomyopathy. While the suspicion of cardiovascular disease is often raised during life in such athletes, the coreect diagnosis is not often made clinically.

IMPACT OF STATEWIDE COORDINATION OF HYPERTENSION CONTROL

C. Manu, State Dept. of Human Services, *State House, Augusta, Maine* 04333

Develop a statewide high blood pressure control coordinating council. Assess the level and type of statewide coordination existing prior to the onset of the project. Assess baseline information on the prevalence of high blood pressure and patient awareness and control levels. Prepare a written high blood pressure control plan to interpret, implement, monitor, and evaluate the program. Collect baseline information describing morbidity/mortality patterns in stroke and hypertension related heart disease. Collect an inventory of resources within the state of Maine

which can be brought to bear on hypertension control. Implement high blood pressure control plan developed. Conduct a follow study to measure changes in levels of coordination, prevalence of awareness about high blood pressure, and morbidity and mortality rates relating to objectives in this Program, which have occurred during the time of the coordination effort.

NATURAL AND EXPERIMENTAL ATHEROSCLEROSIS

J.P. Strong, Louisiana State University, Medical Center, School of Medicine, Dept. of Pathology, *1542 Tulane Ave., New Orleans, Louisiana* 70112 (P01 HL 08974-15)

The ultimate objective of this research is to determine the etiology and pathogenesis of atherosclerosis and its sequelae. This objective is approached by combining morphologic, experimental, epidemiologic, chemical, cytologic and biometric methods. The possible etiologic relationships of certain environmental factors and disease states to arterial lesions, coronary heart disease and sudden death are being studied using a community patholoy approach. This study of a 100 percent sample of deceased men, 25-44 years of age, from the biracial community of New Orleans includes a detailed examination of the heart, coronary arteries, and the postmortem characteristics of the 80 percent of deaths which are autopsied. An explanation for an apparent anomalous difference in coronary heart disease in young Negro and Caucasian men is being sought. Experimental studies in nonhuman primates are being used to study the mechanisms of development and regression of diet-induced arterial lesions. Factors causing variability in rate of development of regression of diet-induced atherosclerotic lesions are being studied. Cholesterol and lipoprotein metabolism is also being investigated in primate animals to obtain an understanding of the mechanisms responsible for the large differences in serum cholesterol or lipoprotein concentration among animals. Tritiated thymidine uptake studies are used to study the role of cell proliferation in the pathogenesis of atherosclerosis. Archived coronary arteries, and associated clinical data obtained from 24,000 autopsies from 19 geographic and racial groups are being used to obtain a better understanding of the natural history of human atherosclerosis and its geographic distribution.

PULMONARY SCOR - AIRWAYS OBSTRUCTIVE DISEASES

B. Burrows, University of Arizona, School of Medicine, Dept. of Internal Medicine, *1501 N. Campbell Ave., Tucson, Arizona* 85721 (P50 HL 14136-07S1)

The work proposed is directed toward meeting the objectives of the Arizona SCOR, i.e., to elucidate the pathogeneses, pathophysiology, natural histories and factors contributing to the development of airway obstructive diseases (AOD) in order to prevent, detect, and/or treat AOD. To accomplish this, seven closely related projects, supported by Core units, comprise a multidisciplinary program involving and combing epidemiological, clinical, pathophysiological, experimental, and radiological approaches to the AOD problem. The prospective longitudinal epidemiological survey of the 4000 members of 1650 Tucson households will continue to study the role of environmental, host, and genetic factors, including atopy, asthma, and history of bronchiolitis or other childhood respiratory illness, in contributing to the risk of developing chronic bronchitis, emphysema, or other chronic obstructive pulmonary disease (COPD), and provides further opportunity to evaluate methods for early detection of subclinical COPD. Air versus helium oxygen flow-volume curves and chest radiographs will be evaluated in this context. In subpopulations, there are specific studies of the role of aeroallergens, atopy and IgE levels, airway reactivity, or alpha-1-antitrypsin Pi MZ phenotype in development of AOD. Pediatric lung function tests are being developed and will be utilized to study childhood airways diseases and their long-term consequences. Experimental studies are being employed to relate structure to function in canine models of AOD and in excised lung preparations and human autopsy material, combining physiological measurements with simultaneous roentgenographic image magnification and subsequent morphometry and refinements of high resolution radiologic imaging will continue.

JOHNS HOPKINS LUNG CENTER - CHRONIC DISEASES OF AIRWAYS

H.A. Menkes, Johns Hopkins University, School of Medicine, Dept. of Medicine, *725 N. Wolfe St., Baltimore, Maryland* 21205 (P50 HL 14153-08)

In the development of chronic obstructive pulmonary disease (COPD) there is a transition period when the individual is asymptomatic and the physician is unaware of the disorder. The present SCOR program includes a collaborative multidisciplinary approach to the study of obstructive lung disease especially during its earliest stages. In the first section of the program epidemiologic and physiologic approaches are applied to investigate the etiology, risk factors, and the natural history of airways obstruction. In the second section, immunologic and physiologic approaches are used to study acute reactions of the airways and their relation to chronic disease. In the third section, pathologic and physiologic approaches are applied to evaluate chronic reactions in the development of airways obstruction. Our goal is to characterize the individual at risk for COPD. With that knowledge, it may be possible to introduce effective modes of intervention.

A/S SCOR--LIPIDS, ATHEROSCLEROSIS AND THROMBOSIS

A.A. Spector, University of Iowa, School of Medicine, Dept. of Internal Medicine, *Jessup Hall, Iowa City, Iowa* 52240 (P50 HL 14230-09)

This is a multidisciplinary research project having a goal of elucidating basic biochemical and pathological mechanisms responsible for arteriosclerotic cardiovascular disease. It is made up of six research projects and two Core laboratories. Project 1 deals with the effect of membrane lipid modification on cell function as well as the regulation of cholesterol and fatty acid biosynthesis in leukocytes. Project 2 deals with the development and regression of atherosclerosis in a primate model. Project 3 deals with the function of human endothelial cells and the interaction between endothelial cells and platelets. Project 4 deals with plasma clotting factors, particularly factor VIII, thrombin, heparin cofactor and the binding of thrombin to cultured endothelial cells. Another aspect of this project deals with the properties of endothelial cells derived from mouse brain blood vessels. Project 5 is a clinical epidemiological project on coronary risk factors in school children. Project 6 concerns the role of lysosomal enzymes in atherosclerosis, with particular attention given to cholesteryl ester hydrolase. These projects are supported by Core laboratories.

IMMUNE & FIBROTIC RESPONSES TO OCCUPATIONAL ENVIRONMENT

H. Weill, Tulane University of Louisiana, School of Medicine, Dept. of Medicine, *1430 Tulane Ave., New Orleans, Louisiana* 70112 (P50 HL 15092-08)

The goal of this SCOR program is to provide the scientific basis for the prevention of fibrotic and immunologic lung diseases which are related to the occupational environment. A multidisciplinary approach is utilized in order to establish causal relationships, dose-response curves, and threshold levels of exposure in lung disorders which are related to the inhalation of mineral and organic dusts, and chemical vapors and gases. Disciplines incorporated in this Center include pulmonary physiology, epidemiology, biostatistics, immunology, chest roentgenography, bioengineering, environmental chemistry and industrial hygiene. Significant emphasis is placed on newer methods of characterizing the inhaled environment which should lead to establishment of those methods which relate best to the indexes of an altered biologic response, and therefore most closely estimate the true exposure dose. The overall significance of this program lies in the fact that these occupational lung disorders are potentially completely preventable, and data from these studies should lead to the establishment of rational occupational environmental standards for hazardous inhalants.

A/S SCOR--EARLY NATURAL HISTORY OF ARTERIOSCLEROSIS

G.S. Berenson, Louisiana State University, Medical Center, School of Medicine, Dept. of Medicine, *1542 Tulane Ave., New Orleans, Louisiana* 70112 (P50 HL 15103-08)

The SCOR-A at LSU is involved in clinical and experimental studies related to the early natural history of Atherosclerosis and Essential Hypertension. The clinical research includes 5,000 children in the Bogalusa Heart Study, a biracial population under examination for extensive risk factor data. The study follows an epidemiologic design which is both cross-sectional and longitudinal. Anthropometric parameters, blood pressure, serum lipids and lipoproteins, reported smoking, and blood glucose are being observed. An interrelationship of these variables shows clustering of multiple risk factor variables beginning in older children. Extrapolation from adult studies, e.g., Framingham, suggests we can detect children with high or low risk for cardiovascular disease. Time-course changes of these variables indicate a high correlation of values from one year to the next indicating a significant 'tracking' is occurring. Children tend to persist in their respective ranks. Special sub-studies related to blood pressure and serum lipoprotein levels are in progress. Interesting bi-racial differences are suggesting different biological mechanisms are involved in changes of risk factor variables. Black children seem programmed for hypertension and white males show significant lipid changes contributing to the early development of coronary artery disease.

Experimental research on a nutritional model in non-human primates produced hyperlipoproteinemia and hypertension. In this model, an influence of sucrose on hypercholesterolemia and an accentuation of blood pressure has been noted. Other studies of the chemistry of the arterial wall have characterized two different proteoglycans which are significantly different from the well-characterized chondromucoprotein. Further studies on proteoglycans as they may interact with fibrous macromolecules are under investigation.

EPIDEMIOLOGICAL STUDY OF ATHEROSCLEROSIS IN EVANS COUNTY

C.G. Hames, Evans County Dept. of Health, *2 N. Newton St., Claxton, Georgia* 30417 (R01 HL 03341-23)

Continue the surveillance of morbidity and mortality, including all clinical cardiovascular and cerebrovascular events; i.e., transitory ischemia, CVA, myocardial infarction along with the collection of pathological specimens and other necropsy data where possible, of all cohort study groups in the Evans County Studies; i.e., a) 1200 participants in NHLI lipoprotein phenotyping study; b) 1,000 black-white neonatal blood pressure study participants; c) 600 stepped vs. regular care participants in the NHLI-HDFP study; d) approximately 1,800 participants of the original 1960 Evans County Study cohort; e) 1,000 oral contraceptive users vs. 1,000 age, race matched non-oral contraceptive users; f) 650 Blacks and Whites typed of G6PD deficiency A, A (-) and B. Correlate the above parameters under study with morbidity and mortality; i.e. a) spectrum of Alpha-beta lipoprotein fractions with morbidity and mortality; b) blood pressure levels during the first year of life as a predictor of subsequent hypertension; c) compare Evans County neonatal black-white blood pressure levels with comparable groups in other geographical areas; i.e. genetic vs. environmental? d) determine differences, if any, in the 5 year survival of stepped care vs. regular hypertensive care in the NLHI Evans County Hypertension Detection and Follow-up Program; e) determine if kallikrein levels, heparin neutralizing activity or estrogen levels are related to morbidity and mortality in black-white oral contraceptive users vs. non-oral contraceptive users. Continue to utilize the already defined as well as new biracial pedigree cohorts for genetic models to study the possible inheritance of hypertension and hyperlipidemias. Maintain the study as a population laboratory for the Dept. of Epidemiology, School of Public Health, Univ. of North Carolina; Duke University; Medical Univ. of S.C. and other collaborative institutions in which to explore the association between the observed CHD and hypertension in the Evans County study population and new untested specific epidemiological correlates.

MULTIPARAMETER METHODS FOR CARDIOVASCULAR RESEARCH

J. Cornfield, George Washington University, Columbian College Arts & Sciences, Dept. of Statistics, *2121 Eye St. N.W., Washington, District of Columbia* 20037 (R01 HL 15191-08)

New statistical methods for multiparametric problems arising in cardiovascular research are to be developed. 1. Lines of development newly initiated during the present grant period, although not originally planned for, are to be extended. These include new methods of analysis in matching studies, including the estimation of the odds ratio in case-control studies; weakly parametric methods of life-table analysis, such as assuming a monotone hazard function, but not its functional form; estimation of the performance characteristics of an estimated classification procedure, such as might be supplied by a sample discriminant function, when applied to a new body of data, as suggested by our work in the computerized interpretation of the ECG; investigation of the characteristics of a multi-hit dose-response curve of possible relevance in estimating low dose level effects of environmental agents that can be experimentally studied only at high dose levels, as suggested by our work with the FDA; and robust multivariate estimation. 2. Lines of development originally planned for during the present grant period are to be further extended. These include development of a model leading to estimates of the effects on disease risk of intermediate, as well as baseline, measurements of risk factors in prospective studies; pull-back estimates in multi-way classifications including contingency tables, in regression, with particular emphasis on step-wise regression and in the appraisal of multiple end-points.

VERMONT LUNG CENTER

J.E. Craighead, University of Vermont & State Agricultural College, School of Medicine, Dept. of Medicine, *85 S. Prospect St., Burlington, Vermont* 05401 (P60 HL 17292-05)

The Vermont Lung Center has as its major objectives: 1. The integration into a cohesive operational system of existing lung programs in research, education, clinical demonstration, and regional disease management, including dissemination of information and technical assistance, health statistics and prevention and control. 2. Interdisciplinary study, prevention and control of pneumoconiosis. 3. Research in the pathology and management of acute pulmonary trauma, in basic methodology of computer-assisted instruction in pulmonary physiology in the pathology, pathogenesis, biochemistry, immunology, and cell physiology of diffuse interstitial lung disease (Vermont SCOR). 4. Clinical demonstration and rapid application of new research findings in lung disease using the Problem Oriented Medical Information System (PROMIS). 5. Regional management of specified lung disease problems utilizing an inter-hospital computer network. 6. Graduate and post-graduate education using audio-visual aids and regional interactive television. 7. Public education and information geared to lung disease problems specified by the regional Lung Disease Management Committee. 8. Provision of a broadly based, multi-disciplinary Training Environment for undergraduate, graduate and post-graduate scientists, physicians, nurses, and allied health professionals in the various facets of research, clinical practice, teaching and continuing education in the biology of the lung, disease of the lung, and health care management of categorical problems related to the lung.

THE IMPACT OF STRESS ON CORONARY HEART DISEASE

M.J. Horowitz, University of California, San Francisco Campus, Langley Porter Neuropsychiatric Inst., *401 Parnassus Ave., San Francisco, California* 94122 (R01 HL 17580-05)

The objective of this study is to determine whether groups of men aged 35-57 exposed to higher-than-usual frequencies of potentially stressful life events tend to have higher death rates, higher rates of coronary heart disease, and higher blood pressure levels and smoking rates, than a comparable contrast group with less exposure to stressful life events. In addition, the study aims to determine whether stressful life events are imposed in an individual as a result of being identified as high risk for coronary heart disease. That is, does the process of being informed of one's risk and, as a consequence, being asked to take preventive measures such as changing diet and smoking behaviors, losing weight, and taking medication for hypertension, operate as a specific stress factor and influence mortality?

CARDIOVASCULAR FITNESS AND OTHER RISK FACTORS

L.D. Cady, University of Southern California, School of Medicine, Dept. of Community Medicine & Pub Hlth, *2025 Zonal Ave., Los Angeles, California* 90033 (R01 HL 18235-03S2)

Prospective exercise examination data for nine thousand employees are being analyzed by multivariate statistical techniques to show the degree of relationship between physical work capacity (PWC 160), oxygen consumption at exercise heart rates of 160 beats per minute and coronary heart disease morbidity in the context of other risk factors (cholesterol, triglycerides, uric acid, hemoglobin, resting and exercise blood pressures, overweight, skinfolds, smoking, age, resting and exercise electrocardiograms, etc). The precise measures of cardiovascular fitness are sensitive to changes in physical activity of ten minutes per day and the reliable ascertainment of cardiovascular events is made possible by complete access to computerized workers' compensation claims files, computerized personnel files, and retirement files.

CARDIOVASCULAR FOLLOW-UP OF HYPERTENSIVE ADOLESCENTS

D.E. Fixler, University of Texas, Health Science Center at Dallas, Southwestern Medical School, Dept. of Pediatrics, *5323 Harry Hines Blvd., Dallas, Texas* 75230 (R01 HL 18456-04)

The natural history of adolescents with blood pressures at or above the 95th percentile has not been well defined. This proposal is a continuation of a cross-sectional prevalence study initiated in 1976, when 10,641 eighth-grade students were screened for high blood pressure. These students will be re-examined as tenth and twelfth graders. The purpose of this study is: 1) to determine the prevalence of hypertension and cardiovascular changes in an older adolescent population; 2) to determine at what age racial differences in the prevalence of hypertension develop among black, whites, and Mexican-Americans; 3) to determine if exercise conditioning has a beneficial effect on the blood pressures of hypertensive adolescents; 4) to determine if exercise stress testing indicates those prone to develop persistent hypertension; 5) to determine the effectiveness of propranolol treatment in hypertensive adolescents and its subsequent alterations on blood pressure response to exercise stress and echocardiographic findings. The hypertensive adolescents have been individually paired with cohorts having blood pressures below the fiftieth percentile and matched with respect to race, age, sex, and body size. The cohorts selected during the eighth-grade screening program have also had exercise stress testing and echocardiographic evaluation of cardiac hypertrophy and function. Those students found to have persistent hypertension during the tenth-and twelfth-grade years will be re-evaluated using these techniques. The blood pressure and electrocardiographic response to exercise stress testing and the echocardiographic findings wwll provide data to determine changes in prevalence of hypertensive myocardial alterations in older adolescents. The exercise training studies will determine whether physical conditioning effectively reduces elevated pressure in the adolescent population.

A large population of hypertensive adolescents has already been identified and had baseline cardiovascular studies. Continuation of this project will provide valuable information on the natural history and response to therapy of early essential hypertension.

EPIDEMIOLOGY AND COURSE OF VIRAL MYOPERICARDITIS

D.J. D'Alessio, University of Wisconsin, Madison Campus, Medical School, Dept. of Preventive Medicine, *307 N. Charles St., Madison, Wisconsin* 53706 (R01 HL 18535-03S1)

Retrospective and prospective studies will be conducted to more fully define the epidemiology and natural history of viral myopericarditis. Acute and convalescent sera from patients with clinically diagnosed myopericarditis, submitted to this laboratory between 1967 and 1975 and sera from the approximately 100 new cases submitted each year, will be tested by microneutralization for a significant antibody rise and/or specific immunoglobulin (Ig) M antibody to Coxsackieviruses B1 through B5. Immunofluorescence and immunoperoxidase techniques, in conjunction with density gradient serum globulin fractionation will be investigated as a more rapid and less complex means of detecting and quantitating specific IgM antibody. The relative importance of the different Coxsackievirus B sero-types to the etiology of myopericarditis and the ratio of this entity to all Coxsackie-virus B induced disease diagnosed by this laboratory also will be studied. We will seek to establish by contacting referring physicians and patients with and without Coxsackie B associated myopericarditis some of the following data: onset data, clinical course and differences between Coxsackie B and non-Coxsackie myopericarditis, descriptive epidemiologic characteristics of the population involved, and the course subsequent to the acute episode especially in regard to the development of chronic cardiac dysfunction. Finally, we will investigate other etiologies likely to be involved in this disease. If the Coxsackie B viruses are responsible for considerable serious cardiac disease, this information would justify efforts to develop a vaccine.

EPIDEMIOLOGIC STUDY OF CHRONIC LUNG DISEASE

M.W. Higgins, University of Michigan, Ann Arbor Campus, School of Public Health, Dept. of Epidemiology, *Ann Arbor, Michigan* 48104 (R01 HL 18632-03)

An epidemiologic study of chronic obstructive lung disease (C.O.L.D.) is being done in the population of Tecumseh, Michigan. It consists of a longitudinal study of morbidity and mortality in persons examined in 1962-65. Follow-up and re-examination of the cohort was carried out between January, 1978 and June, 1979.

The principle objective of the study is to relate findings at the initial examination (risk factors) to subsequent illness, decline in lung function, and death. End points include chronic bronchitis, asthma, emphysema, other C.O.L.D., excessive decline in lung function and death from chronic lung disease and other causes. Risk factors include selected personal, demographic, physiologic, genetic and familial characteristics such as smoking and drinking habits, socio-economic status, experience of respiratory infections and allergic conditions, level of lung function, blood and serum protein type, skin sensitivity to allergens and immunoglobulin levels. The predictive ability of risk factors acting singly and in combination, will be assessed for each end point. Particular attention will be given to interaction between smoking and other relevant factors.

Additional objectives include improvement in diagnostic accuracy of different types of C.O.L.D. in epidemiologic studies, and identification of lung function tests which are most suitable for prediction and early detection of C.O.L.D. in the general population.

THE DETERMINANTS OF RISK OF SUDDEN DEATH

L.E. Hinkle, Cornell University, Medical Center, Cornell Medical College, Dept. of Medicine, *1300 York Ave., New York, New York* 10021 (R01 HL 18776-05)

743 steadily employed men, age 40-65, have been examined comprehensively, with twenty-four hour ECG recordings, studied repeatedly for disorders of cardiac conduction and dysrhythmias, other evidences of heart disease, and potential risk factors and followed prospectively six to ten years with examinations at intervals of six months to four years. One hundred and twenty-one deaths have been investigated intensively, with observational data at the time of death in 114 cases. 74 arrhythmic deaths have been associated with chronic myocardial disease in 95% of cases (ischemia 84%, hypertrophy 83%, dilatation 22%, congestive heart failure 41%, heavy alcohol intake 29%), with acute myocardial disease in 77% of cases (acute ischemic heart disease 59%, sub-acute CHF 7%, acute anoxemia 28%), with chronic disorders of cardiac conduction system in 85% of cases (disorders of rate 34%, of pacemaker 30%, major supraventricular dysrhythmias 20%, conduction delays 32%, prolonged QT 23%, major ventricular dysrhytmias 48%; median, two of these), and with CNS arousal and physical activity. 253 variables in 12 categories of myocardial disease, disorders of rhythm and conduction, other cardiovascular disease, disorders of other organ systems, metabolic disorders, generalized pathological states, intake, premonitory symptoms, activity, behavior, social categories and age, and other general conditions are being analyzed in an attempt to define better the factors that are most predictive of the occurrance of sudden arrhythmic death, death in power failure, and new events of non-fatal heart disease.

PROSPECTIVE STUDIES OF CONDUCTION DISEASE

K.M. Rosen, University of Illinois, Medical Center at Chicago, Abraham Lincoln School of Medicine, Dept. of Medicine, *1853 W. Polk St., Box 6998, Chicago, Illinois* 60680 (R01 HL 18794-05)

This is a continuing study of patients with chronic bifascicular block and intact atrioventricular conduction. Patients are studied clinically, electrocardiographically, and electrophysiologically (His bundle recording, pacing responses, and refractory periods). Attempts were made to delineate clinical, electrocardiographic, and electrophysiologic parameters which predict subsequent risks of AV block and sudden death. If a high risk group were to be defined, attempt at modification of life history with prophylactic pacing would be performed.

PULMONARY SCOR--CHRONIC DISEASES OF THE AIRWAYS

J.D. Brain, Harvard University, Boston Campus, School of Public Health, Dept. of Physiology, *55 Shattuck St., Boston, Massachusetts* 02115 (P50 HL 19170-04)

The goals of this proposed SCOR program are: 1) to generate new knowledge relating to the physiology, pathology, pharmacology, and epidemiolmgy chronic diseases of airways; and 2) to apply this knowledge of to the study of new modalities of therapy and prevention. We seek the effective integration of laboratory and clinical research and its focus on airways disease. Project 1 examines one important reservoir from which clinically significant disease arises, and seeks to explore the progression and reversibility of airways disease. Projects 3, 4, and 5 grapple with major issues of etiology: genetic, physiologic, pharmacologic, and environmental interactions which may provide and accelerate the pathophysiological changes leading to debilitating airways disease. Project 6 examines one of the consequences of airways dysfunction which leads to disability and respiratory failure. With Project 7 we begin to consider interventions; other aspects of disability and approaches to therapy are explored in Projects 8 and 9. The core units (Projects 10 and 11) provide essential services for the described research. We believe these projects represent a significant interdisciplinary attack directed toward chronic diseases of airways.

PULMONARY SCOR:

W.A. Clyde, University of North Carolina, Chapel Hill Campus, School of Medicine, Dept. of Pediatrics & Bacteriology, *Manning Dr., Chapel Hill, North Carolina* 27514 (P50 HL 19171-03)

An integrated, multidisciplinary research program is in progress which has as a general goal the identification and control of acute, intercurrent processes which may influence growth and development of the respiratory system with resultant long-term sequelae. Longitudinal studies of infants and children are establishing normal patterns of growth of lung function and the impact on this of acute respiratory infections with emphasis on the syndrome of bronchiolitis. This prospective clinical study is complemented by retrospective approaches of three types: 1) comprehensive evaluations of patients referred for recurrent or chronic progressive pulmonary diseases (including those with cystic fibrosis, sarcoidosis and anti-protease or immune deficiencies) to identify responsible defects in pulmonary defense mechanisms; 2) follow-up studies of children in the community documented to have had infections during the past decade with agents such as respiratory syncytial virus; and 3) assessment of the burden of pulmonary disability among North Carolina Children by development, testing and validation of pediatric questionnaires to facilitate case finding and early diagnosis. Relevant basic laboratory studies are being performed using experimental models of respiratory diseases (animals and cultures of specialized pulmonary cells infected with representative agents) to define the mechanisms of injury, repair and protection. This combination of clinical and basic research should lead to improve means of diagnosis, therapy and prevention of respiratory diseases and their complications or sequelae.

PROBLEMS IN PREVENTION OF RHEUMATIC HEART DISEASE

E.L. Kaplan, University of Minnesota, Minneapolis Campus, School of Medicine, Dept. of Pediatrics, *1305 Mayo, Minneapolis, Minnesota* 55455 (R01 HL 19307-04)

Rheumatic fever and rheumatic heart disease remain as important causes of cardiovascular disease. The ultimate control of this theoretically preventable disease requires control of preceding streptococcal upper respiratory tract infections. However, important unanswered questions about the epidemiology of streptococcal infections and especially about individual susceptibility to these infections require answers. This study is designed to address these questions. In addition to studying the epidemiology of streptococcal respiratory tract infection (concentrating on the risk of intra-familial spread), this study will evaluate new diagnostic techniques and validate and correlate older techniques used in the diagnosis of this infection. Since it is thought that the carrier of group A streptococci presents both a smaller risk to himself (in terms of developing non-suppurative sequelae of group A streptococci) and to his contacts (less likely to spread the organism to others), it is essential that better techniques be devised to allow clinical differentiation between bona fide group A streptococcal infection and the symptomatic or asymptomatic carrier. This information may ultimately lead to a reduction in the incidence of rheumatic fever and thereby reduce the morbidity and mortality from rheumatic heart disease. The third year of the study will be carried out among index cases of pharyngitis and their family contacts seen in clinic-emergency room setting. Clinical observations and both established and new laboratory techniques will be serially obtained and correlated to assist in identifying and documenting host and bacterial risk factors affecting the epidemiology of streptococcal infections and in differentiating bona fide streptococcal infections from the carrier state.

RESPONSE OF THE LUNG TO INJURY

C. Franzblau, Boston University, School of Medicine, Dept. of Biochemistry, *80 E. Concord St., Boston, Massachusetts* 02215 (P01 HL 19717-03)

Pulmonary emphysema and interstitial pneumonia are two diffuse lung diseases which may be viewed as responses of the lung to injury. One of the identifying features of emphysema is the specific alteration of the elastic tissue network, whereas in interstitial pneumonia, widespread involvement of many of the elements of the pulmonary parenchyma occurs. Understanding the nature of these processes has been limited in early stages of disease. We propose to study animal models of emphysema and diffuse interstitial pneumonia in a concerted attempt to gain insights into the pathophysiological and patho-biochemical changes which takes place in these progressing lesions. Lung mechanics and gas exchange will be examined. Connective tissue biochemistry, prostaglandins, catecholamines and cyclic nucleotides will be evaluated, and the full range of ultrastructural techniques will be applied to the various lesions. Modified elastases will be synthesized to study in these animal models. Studies on pure cell systems from lung will provide additional insights. In parallel studies, an assessment of lung growth and development in normal and pneumonectomized animals will be carried out employing many of the same physiologic, biochemical and ultrastructural techniques. Radioautography at the light and electron microscopic level are an integral part of all animal studies. The possible role of cell mediated immunity in the pathogenesis of these diseases will be investigated. A laboratory devoted to clinical epidemiological studies will interrelate with several of the medical science disciplines represented in the program. It is anticipated that the results of all these studies will give rise to greater understanding of processes of normal lung growth and the nature of the injuries and their repair which results in the development of pulmonary emphysema and chronic interstitial pneumonia. New diagnostic and therapeutic techniques may well derive from these studies.

PREVENTION OF PROSTHETIC VALVE ENDOCARDITIS

G.L. Archer, Virginia Commonwealth University, Medical College of Virginia, Dept. of Medicine, *1200 E. Broad St., Richmond, Virginia* 23298 (R01 HL 19818-04)

The proposed research will investigate methods for prevention of prosthetic valve endocarditis (PVE) caused by the bacterium, Staphylococcus epidermidis, the most common organism causing these infections. The study will involve three phases. In the first phase, the antibiotic susceptibility of isolates from patients with PVE will be determined, mechanisms of antibiotic resistance investigated, and the antibiotic susceptibility characteristics of the organisms related to time of onset of infections following surgery and the antibiotic prophylaxis used in each patient during surgery. In the second phase, antibiotic prophylaxis will be studied using a rabbit model of endocarditis. The value of prophylaxis in preventing infections due to antibiotic-resistant S. epidermidis and in selecting out these resistant isolates will be evaluated. The final phase of the study will be to define the hospital epidemiology of S. epidermidis and the methods of transmission of this organism to patients. Specific markers for hospital-acquired S. epidermidis will be sought using new epidemiologic tools, particularly those which characterize patterns of extrachromosomal DNA.

BLOOD PRESSURE--PRECURSORS AND CONSEQUENCES

R.L. Watson, University of Mississippi, Medical Center, School of Medicine, Dept. of Preventive Medicine, *2500 N. State St., Jackson, Mississippi* 39216 (R01 HL 19858-04)

In this study we will reexamine selected samples of a cohort of women formed during 1965-1967, as well as children born to this cohort.

A portion of these women who had blood pressure measured during a school survey at the ages of 14 to 20 subsequently pregnant, and some developed preeclampsia. They delivered children now 6-11 years of age. Reexamination of the mothers and examination of the children is planned to determine if blood pressure of children of mothers in whom preeclampsia was diagnosed differs from those of mothers in whom no such diagnosis was made.

Urinary electrolytes, dietary histories, socioeconomic levels and other information, as well as repeat blood pressure determinations, were obtained in other subsamples of the school cohort. Reexamination is planned to determine the correlation of the previously obtained variables with present blood pressure status. In addition, siblings previously characterized will be reexamined to allow analysis of blood pressure aggregation in the face of the establishment of separate households and differing environmental patterns with time.

EPIDEMIOLOGICAL STUDIES, PRECURSORS OF HYPERTENSION

B.J. Van den Berg, University of California, Berkeley Campus, School of Public Health, Dept. of Sociology & Administrative Health Sciences, *Berkeley, California* 94720 (R01 HL 19859-04)

Our epidemiologic research, aimed at the identification of precursory factors for high blood pressure in young persons, is based on longitudinal observations of blood pressure and of concomitant variables of mothers and their children.

The bases for our research are twofold. First, we plan to use the extensive data that have been collected in a prospective, longitudinal cohort study, which started with some 20,000 pregnant women and proceeded with observations on the children born from these pregnancies. Secondly, we plan to extend our observations with a follow-up examination of a subcohort of about 2,000 mothers and their children when the latter are about 16 years old. Parallel to this examination we plan a medical record review of parents and child. A large part of the data has already been assembled and is maintained as a research tool by the Child Health and Development Studies (CHDS).

The basic study cohort of CHDS consists of some 20,000 pregnant women and the children born from these pregnancies. The families resided in the San Francisco Bay Area and were members of a prepaid medical plan, Kaiser Foundation Health Plan, which provides comprehensive medical care for the entire family.

The Child Health and Development Studies were designed and initiated in 1959 by Dr. J. Yerushalmy,

and are a research unit of the School of Public Health, University of California at Berkeley.

ASTHMA EPIDEMICS AND ENVIRONMENT-WHEN, WHERE AND WHY
T.F. Goldstein, Columbia University, School of Public Health, Dept. of Epidemiology, *600 W. 168th St., New York, New York* 10032 (R01 HL 25793-01)
The objective of this study of epidemic asthma is to develop models enabling the predictions in time and space of asthma epidemics by first: finding reliable and objective procedures for identifying such epidemics, second: to examine and interpret long-term trends in asthma, third: to identify environmental factors including pollutants both man made and biological and meteorological parameters associated with the epidemics.
The procedure will use data from municipal hospital emergency rooms in New Orleans and New York City, meteorological and demographic data, and such information as is available on industrial pollutants or natural allergens as seems relevant. Appropriate statistical techniques for time series analysis and cluster analysis have already been developed by the group, and additional techniques will be developed as needed.

DIABETES AND CARDIOVASCULAR RISK IN MEXICAN AMERICANS
M.P. Stern, University of Texas, Health Science Center at San Antonio, South Texas Medical School, Dept. of Medicine, *7703 Floyd Curl Dr., San Antonio, Texas* 78284 (R01 HL 24799-01)
Historically, new facts and/or hypotheses bearing on the etiology, pathogenesis, and/or prevention of disease have often been discovered by epidemiological investigation of previously unstudied population with distinctive genetic and cultural attributes. Mexican Americans are such a population. There is reason to believe that this population developed a high prevalence of obesity and diabetes mellitus as it underwent a historic change from food scarcity to relative food abundance. There is also evidence to suggest that this situation may now be changing, i.e., that there may be a 'descending limb' to the rising affluence, rising obesity and diabetes curve.
We plan to study the distribution of 'diabetic pattern' (i.e., glucose intolerance, obesity, hypertriglyceridemia and perhaps also alpha-lipoprotein levels) and other cardiovascular risk factors in 2400 Mexican Americans and 1600 Anglos randomly selected from 6 census tracts in San Antonio, Texas. These tracts have been chosen so as to represent three socially and ethnically diverse regions of the city: a highly traditional, almost exclusively Mexican American neighborhood ('barrio'); an ethnically integrated area ('bicultural'); and a predominantly Anglo region ('suburbs'). We postulate that Mexican Americans will be progressively move acculturated to mainstream U.S. culture as one mores from the barrio to the suburbs, thus enabling us to test our basic hypothesis that 'diabetic pattern' cardiovascular risk factors vary inversely with degree of acculturation.
Cardiovascular risk factors to be measured include glucose intolerance, obesity, lipids, lipoproteins, blood pressure, and smoking history. Acculturation-related variables include generational status in the U.S., culture of upbringing, language patterns, familism, social mobility, and dietary patterns.
We will also evaluate the possibility that a criterion for diagnosing diabetes based on glycosylated hemoglobin may be superior to presently available criteria for use in epidemiological studies.

PHYCHOSOCIAL FACTORS AND CHRONIC DISEASE
J.S. House, University of Michigan, Ann Arbor Campus, School of Public Health, Dept. of Epidemiology, *Ann Arbor, Michigan* 48104 (R01 HL 24545-01)
This project seeks to ascertain the relationship of psychosocial factors to chronic disease, risk factors, morbidity, and mortality through cross-sectional and prospective analyses of data from the Tecumseh Community Health Study. Interview and questionnaire data on psychosocial stress and satisfaction in work, family, and leisure activities will be related to medical examination and interview data collected at the same time (1967-1968) on chronic disease morbidity and risk factors and to mortality over the succeeding decade, through 1978. Controls will be introduced in major analyses for medical examination evidence of health status prior to 1967. Coronary heart disease, hypertension and chronic bronchitis will be focal concerns in cross-sectional analyses of morbidity and risk factors while cardiovascular diseases and cancer will be the major foci of prospective mortality analyses. The analyses will examine not only the direct relationship of work, family, and leisure stress and satisfaction to chronic disease, but also the extent to which these relationships are conditioned or modified, by a variety of individual and social factors (e.g., age, sex, work motivation and involvement, personal habits such as exercise, social support and integration). The relative and joint effects on chronic disease of work and nonwork sources of stress and satisfaction will be assessed.

CLEARANCE OF MAGNETIC DUST FROM LUNGS OF SMOKERS
D. Cohen, Massachusetts Inst. of Technology, Francis Bitter National Magnet Lab., *170 Albany St., Cambridge, Massachusetts* 02139 (R01 HL 24540-01)
In a recent pilot study, we measured long-term pulmonary clearance in a small group of smokers and non-smokers; a one-time inhalation of magnetic dust was used as a harmless tracer. This dust was cleared much slower in smokers than in non-smokers; after one year, five times as much dust was retained in the lungs of smokers as in non-smokers. This higher retention may be one cause of the high rate of pulmonary disease experienced by smokers. We propose to further investigate this result with a larger three-part study. In the first part, a magnetic tracer dust will again be inhaled, and clearance will be measured with more elaborate techniques; six heavy and three ex-heavy smokers (of high tar-nicotine cigarettes), three heavy smokers (low tar-nicotin), and three non-smokers will be studied. Our purpose is to determine if this high retention (and attendant risk) is a function of nicotine-tar content, and if it declines to non-smoker levels in ex-smokers. In the second part, magnetic dust content will be measured in the lungs of ten heavy smokers and ten non-smokers, all with long exposure to urban dust. Also, the same measurements will be made of ten smoking and ten non-smoking arc welders. The purpose is to determine if the higher dust retention seen in smokers also occurs in individuals experiencing normal urban living or during occupational exposure. In the third part, the dust content from sections of autopsied lungs will be measured both magnetically and chemically. At least 150 cases divided into smokers and non-smokers, and including many urban dwellers, will be studied. The purpose is to correlate the amount of magnetic dust to total dust in the lung, and to lung pathology. This will determine if magnetic measurements are a good index of total retained dust, and of lung pathology.

EPIDEMIOLOGY OF ATHEROSCLEROSIS
B.A. Kottke, Mayo Foundation, *200 1st St. S.W., Rochester, Minnesota* 55901 (R01 HL 24489-01)
Herein is described a genetic epidemiological study of the role of variation in lipoprotein phenotypes and lipid fractions in determining certain forms of atherosclerotic disease. This study will be based on 4,565 individuals in three different sets of pedigrees collected as part of the Rochester SCOR program in atherosclerosis (1971-1977). Pedigrees will be analyzed to provide insight into appropriate intervention strategies. In particular, we shall: l) determine the contribution of genetic and environmental variability to lipid variability within and among families; 2) test for heterogeneity of the genetic and environmental contributions to lipid variability among sets of families identified by probands with different lipid levels, quantitative lipoprotein phenotypes or atherosclerotic disease; 3) search for evidence of segregation at one or more loci with major effects on the lipid phenotype; 4) assess the relative risks of atherosclerotic disease in the adult relatives of different types of probands; and 5) relate sources (shared environment, shared polygenes and/or shared major loci) of familial aggregation of lipid phenotype to the risk of atherosclerotic disease.

CHD INCIDENCE, MORTALITY, RISK FACTOR RELATIONSHIPS
L.T. Kurland, Mayo Foundation, Dept. of Medical Statistics & Epidemiology, *200 1st St. S.W., Rochester, Minnesota* 55901 (R01 HL 24326-01)
Medical care for the population of Olmsted County, Minnesota, is almost entirely provided by the Mayo Clinic and the Olmsted Medical Group and their affiliated hospitals. The records of these institutions and other outside sources have been assembled into a single diagnostic retrieval system and provide a unique resource for population-based epidemiologic studies of serious chronic disease.
Under the Rochester Epidemiologic Program Project (GM 14231), we are now completing a Coronary Heart Disease (CHD) study which will establish the local incidence rates for first manifestations of CHD under the subgroups angina pectoris (AP), myocardial infarction (MI), and sudden unexpected death (SUD) over the period 1950-1975. In that study we have 100% follow-up for five years nd 99.6% follow-up to 1/1/76, a 60% autopsy rate in the AP and MI groups, and 86% in the SUD group. Preliminary date indicate only minor changes in CHD incidence, improved survivorship in AP, and during the last ten years a dramatic decrease in the MI case fatality.
In order to obtain a better estimate of the contribution of changing incidence and survivorship to the decreasing mortality rate, we must expand the study from those MIs which are first diagnoses of CHD to all MIs occurring in the local residents. In addition, we propose to extend the coverage from the city of Rochester (current population 55,000) to all of Olmsted County (90,000). Finally, we propose to carry the entire study forward through 1982. Also, all local deaths are being uniformly re-coded to the ICDA 8th revision for the period 1960-1967; this should also be extended to cover 1950-82.
Olmsted County, Minnesota, is an ideal community for the studies proposed, since the medical recodes are of uniform high quality, cover the population of the county with excellent case ascertainment, and are already assembled and retrievable by diagnosis.

LIFE STYLE AND CHRONIC DISEASE IN COLLEGE ALUMNI
R.S. Paffenbarger, Stanford University, School of Medicine, Dept. of Family Community & Preventive Medicine, *Stanford, California* 94305 (R01 HL 24133-01)
This epidemiologic study extends observations on 30,000 living former students from Harvard and 13,000 from the University of Pennsylvania to identify patterns of physical activity conducive to the avoidance or delay of hypertensive-arteriosclerotic diseases in middle life. Prospective observations utilize both historical and ongoing perspectives to: l. Identify the type, frequency, duration, and intensity of activities that predispose to reduced risk of first heart attack, stroke, and other cardiovascular diseases primary prevention. 2. Examine changes in physical activity patterns and other key aspects of life style for their relationships to heart attack risk. Patterns of exertion favoring coronary well-being will be studied in successive age group ranging 45-80 years. 3. Test competing hypotheses of benefit, (a) protection vs. selection and (b) average vs. peak levels of energy output. 4. Assess patterns of physical activity associated with prevention of heart attack recurrence and with survival (secondary prevention). 5. Examine sociopsychological and other risk factors for confounding and interacting with physical exercise in relation to heart attack risk; and 6. search for associations between life style and other specific chronic diseases, fatal and nonfatal.
Two-page mail questonnaires are used to log physical activity patterns, social habits, and health status of college alumni. Responses supplement data already compiled from college physical examination

and other records (1916-1950) investigative and followup mail questionnaires (1962 or 1966, 1972, 1977 or 1978), and official death certificates (1916-date).

COMMUNITY SURVEILLANCE OF CARDIOVASCULAR DISEASE

H.W. Blackburn, University of Minnesota, Minneapolis Campus, School of Public Health, Laboratory of Physiological Hygiene, *1325 Mayo Memorial, Minneapolis, Minnesota* 55455 (R01 HL 23727-01)

Major trends in cardiovascular disability, illness and death occur in this country which are neither explained nor predicted, nor are they readily amenable to explanation by retrospective analysis. It is essential to any rational public health policy and plan that an advanced society explain the evolution, at times almost revolution, in chronic disease experience. It is likely that much of the cardiovascular disease experience is influenced by known, or strongly suspected, socioeconomic, environmental, cultural and behavioral factors. These and their physiological manifestations can be measured. It is therefore feasible and desirable to attempt surveillance and analysis of measurable aspects of health behavior, socio-economic indicators, risk characteristics and disease experience - in parallel - within defined geo-political or trade areas.

This application proposes such a monitoring system which would be thorough, systematic and on-going, involving a smaller-than-national unit, the Twin Cities of Minnesota, over the years 1979-83. The potential advantages of this local approach appear to us to be the depth, detail, and control possible, using manageable-sized teams and samples. Moreover, divergent or opposing mortality and morbidity forces, might be less likely operative than with nationwide sampling. Parallel trends or lag periods between socio-cultural changes and disease experience might be detected, and specific hypotheses examined about change. Within such a dedicated research program, disease trends, and risk factor changes would be identified, and methodological approaches developed, for application by other agencies.

LIFE CHANGE STRESS AND SOMATIZATION IN HYPERTENSION

H.F. Myers, C.R. Drew Postgraduate Medical School, School of Medicine, Dept. of Psychiatry & Human Behavior, *1621 E. 120th St., Los Angeles, California* 90059 (R23 HL 23522-01)

Essential hypertension has been recognized as a major health problem in the United States, with particular impact on blacks, the poor and on women. The present study addresses the role that stressful life change events, subjective appraisal and somatic response patterns play in essential hypertension. The study specifically addresses the following objectives: (1) to determine whether stressful life change events are positively related to and account for a significant proportion of variation in blood pressure; (2) whether subjective appraisal of stress affects blood pressure singly or in interaction with the objective measure of stressful events; (3) to determine whether variations in blood pressure are positively correlated with distinct patterns of somatic response patterns especially a cardio-respiratory response tendency, and finally; (4) whether personal and familial history of cardiovascular difficulties and other socio-demographic factors such as sex, age and race contribute to explaining variation in blood pressure.

The study is designed as a survey study with a random sample of 300 adults, ages 21-65. These subjects will be paid volunteers who will undergo a 1 hour private interview in their homes during which time four blood pressure readings will be taken and a composite questionnaire with scales measuring the predictor variables will be administered. The degree of relationship between the predictor variables (i.e., correlations) and the extent to which they contribute singly or in consort to the proportion of explained variation in blood pressure (i.e., multiple regression analysis) will be ascertained.

DETERMINANTS OF CHD RISK FACTORS IN ADOLESCENCE

G. Christakis, University of Miami, School of Medicine, Dept. of Epidemiology & Public Health, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152 (R01 HL 23356-01)

This proposal constitutes a cross-cultural cohort study of seven defined representative populations of adolescent subjects in order to quantitate and evaluate demographic, psycho-social, dietary and lipid variables which may contribute to later coronary heart disease (CHD) risk. The study cohorts have been chosen to permit comparisons between adolescents residing in a country of highest and lowest CHD incidence (USA and Greece, respectively), those who live in rural and urban areas (rural-urban transition), and adolescents who were born in the country of low incidence, but who have immigrated with their parents and are exposed to the socio-nutritional environment of the high CHD incidence country.

The endpoints of the study are of a 'risk factor' nature, that is the 'tracking' of lipid variables for a period of three years for three different age groups in order to include what is hypothesized to be a critical period in the pathogenesis of coronary arteriosclerosis (i.e., ages 9 through 17). A nexus will be effected between the lipid and other variable status of the study subjects, with sub-population, age-matched, geography-matched individuals who died accidentally, from whom coronary and aorta arterial tissue will be assessed for type and degree of fatty streaks and fibrous and/or arteriosclerotic vessel involvement.

This study will not only serve to Study associations between cohort subjects and their early CHD risk factor status, but will seek to develop an integrative assessment of how the host and environmental variables studied may contribute to, or protect against later CHD risk. Finally, it is also aspired that new hypotheses regarding intervention strategies in childhood and adolescence may be developed which prevent adult CHD.

GENETICS OF HYPERTENSION AND ASSOCIATED VARIABLES

R.M. Siervogel, Wright State University, School of Medicine, Dept. of Pediatrics, *Colonel Glenn Hwy., Dayton, Ohio* 45431 (R01 HL 23194-03)

High blood pressure, including essential hypertension, is a major risk factor of stroke, congestive heart failure, coronary heart disease and other cardiovascular diseases. The identification and study of childhood precursors of hypertension which could lead to methods effective in the prevention of adult hypertension is a major goal of the National High Blood Pressure in the Young Program, Epidemiology Branch, DHVD, NHLBI, of which this study is a part. Considerable evidence suggests that heredity plays a large and important role in determining blood pressure, particularly as it relates to essential hypertension. In the proposed study the mode of inheritance of genes involved with blood pressure regulation and associated variables will be investigated with an aim to providing information relevant to the epidemiology of hypertension. Particular attention will be paid to a search for major genes by using recently developed statistical methods designed for segregation and linkage analysis of quantitative traits in large pedigrees.

Five large (75-350 members) families have been ascertained, each through a proband with essential hypertension; four of these families are White and one is Black. Most members participated in an extensive data collection protocol involving variables of an anthropometric, biochemical, genetic, medical, physiological, psychological and sociological nature. Among the measured variables are: subcutaneous fat thicknesses; plasma lipid, lipoprotein and renin levels; urinary kallikrein and aldosterone levels; genetic markers (blood types, etc.); physical examination and clinical laboratory findings: systolic time intervals in response to numerous stresses; personality assessments; and socioeconomic status.

The identification of genetic effects including major gene influences in variables related to essential hypertension may help define important epidemiologic factors that: 1) relate to increased risk of hypertension; 2) account for differences in blood pressure among various subgroups of the population; 3) can identify children that have high risk for developing hypertension; 4) can identify homogeneous groups for further study of disease etiology.

PSYCHOSOCIAL STRESS AND SUDDEN CORONARY DEATH

W. Ruberman, Health Insurance Plan of Greater New York, Dept. of Research & Statistics, *625 Madison Ave., New York, New York* 10022 (R01 HL 23078-02)

This research seeks to study a large differential in risk of sudden coronary death that has been found among men of relatively low and high educational levels. The setting is a prospective study of men with coronary heart disease among a population of 120,000 men aged 35-74, insured for medical care in New York City (Health Insurance Plan of Greater New York --HIP). Among a cohort of 1,739 men with prior myocardial infarction (MI), those demonstrating complex ventricular premature beats (VPB) in one hour of ECG monitoring show a cumulative probability of sudden coronary death, over a 5-year period, that is more than twice that experienced by the men free of such VPB. Further, among the men demonstrating complex VPB (early, runs, bigeminal or multiform VPB) in one hour, the least educated men are apparently at more than twice the risk for sudden coronary death shown by those with more than eight years of schooling.

The finding with respect to education is not explained by associations with a large number of other variables. This study will examine whether low education reflects a relatively high level of life-situation factors which, given the presence of complex VPB, may trigger the lethal arrhythmia mechanism. Information to characterize the MI patients is being obtained through a telephone interview of spouses of all patients -- both living and dead -- in the original HIP study of VPB and sudden death. Analyses of the interview data will be directed to classification of broad levels of psychosocial stress. Such categories will then be examined as one or more prognostic variables in assessing risk of sudden coronary death controlling for all other important factors. The existence of an extensive body of prognostic information about the large cohort of post-MI men provides an important resource in the analysis of the new psychosocial data.

MULTICENTER POSTCORONARY RISK STRATIFICATION PROGRAM

A.J. Moss, University of Rochester, School of Medicine & Dentistry, Dept. of Preventive Medicine & Community Health, *601 Elmwood Ave., Rochester, New York* 14627 (R01 HL 22982-02)

The proposed research is a multicenter prospective study to develop and validate widely applicable criteria for stratifying risk of cardiac death in the year following acute myocardial infarction. A homogeneous population (acute myocardial infarction) derived from a heterogeneous group of hospitals (university and community) widely dispersed in geography (New York, St. Louis, Rochester) will be studied to permit generalization of the results to the whole population at risk. Three special studies have been included in the clinical evaluation of the postinfarction population prior to hospital discharge: radionuclide ejection fractions for quantitative evaluation of left ventricular function, 24-hour Holter ECG tape recordings for the precise quantitation of the degree of electrical instability, and limited activity tests to assess overall cardiovascular function and the presence of activity-related myocardia ischemia.

Approximately 1000 patients who survive the early hospital phase of an acute myocardial infarction will be entered during a 24-month enrollment period. Routine clinical evaluation and special studies will be performed prior to hospital discharge. All patients will be followed for a minimum of one year with clinical follow-up evaluation at 3, 6 and 12 months. A standard Bruce-protocol exercise will be obtained at the three month follow-up visit. The main thrust of the data analysis are: 1) to identify functional risk variables which can be widely applied to risk stratification

in postinfarction patients; 2) to elucidate pathophysiologic mechanisms responsible for survival and cardiac death by uncovering interactions and associations among the risk indicators; 3) to critically evaluate existing clinical concepts involving postinfarction patients by testing a priori hypotheses on this prospective population; 4) to characterize current patterns of therapy in postinfarction patients to improve background information for the design of future therapeutic intervention trials, and 5) to classify mortality events carefully as to chronology, cause and preventability.

POST-TRANSFUSION HEPATITIS IN NEWBORN CHILDREN

C.E. Stevens, New York Blood Center of Greater N.Y. Community Blood Coun., Laboratory of Epidemiology, *310 E. 67th St., New York, New York* 10021 (R01 HL 22838-02)
The purpose of this project is to evaluate the incidence and etiology of post-transfusion hepatitis in newborn babies. Babies who recieve blood transfusions, primarily premature infants, and non-transfused control babies, are followed for six months after transfusion or hospitalization. Blood specimens are collected monthly during follow-up and are tested for alanine aminotransferase (ALT) level as evidence of hepatitis. Sera are also tested for serologic evidence of hepatitis A and B virus, cytomegalovirus or Epstein-Barr virus infection and are stored for testing of non-A non-B hepatitis agents which may be identified in the future. The goal of the project is to complete prospective follow-up of 200 recipients and 200 controls. The incidence and etiology of hepatitis will be compared in the two groups of babies and with data from a similar study (part of the Transfusion Transmitted Viruses Study) conducted among adults in the same institution.

EARLY RISK PREDICTORS FOR CHRONIC PULMONARY DISEASE

I.B. Tager, Harvard University, Boston Campus, Peter Bent Brigham Hospital, *721 Huntington Ave., Boston, Massachusetts* 02115 (R01 HL 22528-03)
The present proposal is the continuation of the annual follow-up of a cohort of children aged 5-9 years and their family members. The objective of the study is to identify risk factors for obstructive airways disease which operate early in life.
To date it has been determined that: 1) 'high' risk families, as defined in this study, have lower levels of pulmonary function than other families. 2) Parents' cigarette smoking is associated with both lowered level of pulmonary function and an increased prevalence of wheezing in their children. 3) childhood respiratory illness appears to have limited impact on levels of pulmonary function in children in this study. 4) There is a very high year-to-year correlation in age, sex, height standardized pulmonary function in children suggesting that some children with relatively impaired pulmonary function are not likely to outgrow their lowered levels of function.
In the coming year continued screening of the cohort will occur. Analysis will focus on factors influencing the changes in level of function in growing children.

ESTABLISH AN INFECTIOUS ENTERIC DISEASE STUDY CENTER

A.S. Monto, University of Michigan, Ann Arbor Campus, School of Public Health, Dept. of Epidemiology, *Ann Arbor, Michigan* 48104
An infectious Enteritic Diseases Study Center will be established at the University of Michigan. Incidence and etiology of disease will be determined in normal families and in hospitalized cases. The families will be randomly selected from the population of Tecumseh, Michigan. Efforts will be made to identify bacterial, viral, and parasitic agents associated with these illnesses. Serologic techniques will be used to determine infection rates on a uniform basis in the entire study population. New methods will be developed for recognition of infectious agents and for studying mechanisms of pathogenesis. The ultimate aim will be control through therapy and prophylaxis.

EVALUATION OF OCCURRENCE OF INFLUENZA & VACCINE EFFICACY

A.S. Monto, University of Michigan, Ann Arbor Campus, School of Public Health, Dept. of Epidemiology, *Ann Arbor, Michigan* 48104
Specimens for virus isolation will be collected in the community of Tecumseh to identify the appearance of influenza virus in this well-defined population. To study past history of seeding or the occurrence of influenza viruses other than the prevalent strain in the community, the collected sera will be tested against antigens of various type A influenza viruses. To determine current and future patterns of infection, approximately 1000 individuals resident in Tecumseh will be recruited for prospective study. The aim here will be to follow a significant number of individuals of all ages to determine the effect of vaccination, the fall off in antibody level induced over time, the seeding of influenza viruses into the community, and the distribution of infection according to antibody status.

ECOLOGY OF A RECENTLY IDENTIFIED PATHOGENIC VIBRIO SP

J.D. Oliver, University of North Carolina, Charlotte Campus, School of Science & Mathematics, Dept. of Biology, *Hwy. 49 N., Charlotte, North Carolina* 28205 (R01 AI 17059-01)
The Center for Disease Control in Atlanta recently reported on a new species of a halophilic, lactose-fermenting Vibrio (L-plus Vibrio) which has been implicated in fatal cases of septicemia in man. Unlike the enteropathogen V. parahaemolyticus, to which it is closely related, this organism has been isolated from patients with severe tissue infections and extraintestinal lesions. Recent studies from this laboratory have shown that when the L-plus Vibrio is injected subcutaneously (s.c.) or intraperitoneally (i.p.) an extremely potent vascular permeability factor is produced which results in massive generalized edema. The acute vascular fluid loss leads to rapid and profound increases in hematocrit value, with death in experimental mice resulting in 3-6 hours from circulatory failure. The LD50 value in mice (ca. 8 times 10 to the 5th power cells injected i.p.) is two orders of magnitude less than that observed for V. parahaemolyticus. S.c. inocula in mice resulted in severe local infections, and for those surviving longer than 48 hours, tissue necrosis. These animals rapidly developed Vibrio bacteremia after injections. V. parahaemolyticus produced no morbidity or mortality when injected s.c. Injections of L-plus Vibrio into ligated ileal loops in rats and rabbits consistently proved to be lethal with a high density bacteremia resulting.
Because of the potential health hazard present if the L-plus Vibrio exists at any significant level in public beach waters, the present proposal describes studies which are attempts to characterize the distribution of the L-plus Vibrio along the eastern coast of the United States. The microbiological, chemical and physical factors affecting the ecology of the organism will be investigated. Samples to be examined include water, sediment, plankton, and shellfish at each of these sites. Because of their clinical importance, the presence in these samples of two related Vibrio species, V. parahaemolyticus and V. alginolyticus, will also be monitored.

VIRULENCE FACTORS OF E. COLI ENTEROTOXIGENIC FOR MAN

D.G. Evans, University of Texas, Health Science Center at Houston, School of Medicine, Dept. of Clinical Microbiology, *Box 20036, Houston, Texas* 77025 (R22 AI 13385-04)
Enterotoxigenic Escherichia coli, or ETEC, are a major cause of secretory diarrhea in man. ETEC

belonging to the most frequently isolated serotypes and producing both the heat-stable enterotoxin and the heat-labile enterotoxin have been found to produce fimbrial surface-associated antigens which play a major role in the pathogenesis of ETEC diarrhea. These antigens are called colonization factors because these fimbriae promote colonization of the intestinal mucosa by ETEC by an adherence mechanism. Two major colonization factor antigens have been discovered; these are CFA/I which is produced by serotypes 015:H11, 025:H42, 063:H-, 078:H11, 078:H12 and others, and CFA/II which is produced by serotypes 06:H16, 08:H9 and others. The work proposed here seeks to discover which ETEC antigens (heat-labile enterotoxin, somatic antigens, or colonization factor antigens) are relatively most important in stimulating immunoprotection against ETEC diarrhea. Also, immunity against ETEC diarrhea will be investigated in terms of the class of immunoglobulin (IgG, IgM, IgA, secretory IgA) involved in protection. Since ETEC diarrhea is characterized by colonization of the mucosal surfaces without invasion of host tissue it will be important to investigate antibody responses which occur in external secretions; i.e. small bowel fluids, saliva and milk. Epidemiological investigations will be continued and extended to include the question of immune responses arising as the result of natural or artificial exposure to ETEC. Hospitalized volunteers will be employed to approach specific questions concerning the immune response to ETEC. In addition, in vitro studies will be performed using human intestinal epithelial cells in tissue culture to study adherence of CEA-positive ETEC.

EPIDEMIOLOGY OF HEPATITIS B ANTIGEN AND VIRAL HEPATITIS

V.M. Villarejos, Louisiana State University, Medical Center, School of Medicine, Dept. of Tropical Medicine, *1542 Tulane Ave., New Orleans, Louisiana* 70112 (R01 AI 12910-03S1)

In the third grant year it is proposed to continue and expand studies on the epidemiology of type B hepatitis.

Through surveillance and case finding, the epidemiological patterns of occurrence and mode of spread of type B hepatitis will continue to be studied, with emphasis on the definition of mechanisms of transmission and the role of chronic HBsAg carriers in the dissemination of the disease. Comparable data will be obtained for type A hepatitis.

The role of saliva as a vehicle of transmission of type B hepatitis will be investigated further. The infectivity potential of HBsAg carriers and acute hepatitis cases will be defined.

Studies will be conducted on patterns of serologic response in type B hepatitis, including investigation of the behavior of surface and core antigen, e-antigen and e-antibody. The serologic studies of type B hepatitis will be continued.

The investigation of anti-DNA in viral hepatitis will be pursued further.

IMMUNOLOGICAL STUDIES IN STREPTOCOCCAL SEQUELAE

J.B. Zabriskie, Rockefeller University, Bacteriology & Immunology Lab., *66th & York Ave., New York, New York* 10021 (R01 AI 14361-03)

The immunological basis for the pathogenesis of rheumatic fever is generally accepted, but the detailed mechanisms are not clear. Studies are being extended to determine the degree and duration of specific lymphocyte reactivity to streptococcal antigens in rheumatic fever patients as compared to nephritics and controls. Our initial data suggest that rheumatics respond primarily to antigens from streptococcal strains isolated and associated with the disease and not to antigens associated with nephritogenic strains. To further clarify this observation, various antigenic extracts from different strains are being tested.

Further studies on the immunogenetics of rheumatic fever are being carried out with typing of rheumatics, nephritics, controls and their families for B-alloantigens. A high degree of correlation with a new antisera, 6623, has been made with rheumatics from Bogota, Colombia and the New York area. This is being extended to the relatively closed and racially distinct population in Trinidad.

The protein of MN 48,000 found recently to be excreted by streptoccal strains associated with nephritis will be purified in larger quantities for further characterization and development of an RIA system to detect antibodies to this protein in nephritis. Immune complexes found in large amounts in poststreptococcal sequelae and especially nephritis will be examined for the presence of this material.

ENDEMIC SCHISTOSOMIASIS AND CHAGAS' DISEASE IN BRAZIL

T.H. Weller, Harvard University, Boston Campus, School of Public Health, Dept. of Tropical Public Health, *55 Shattuck St., Boston, Massachusetts* 02115 (P01 AI 16305-01)

The research program is a multidisciplinary collaborative effort in Salvador, Brazil, with a primary focus on the clinical evolution, immunopathology, and epidemiology of Manson's schistosommiasis and of Chagas' disease. Three Harvard scientists, stationed in Brazil, engaged in collaborative research with counterparts from the Faculty of the Medical School of the Federal University of Brazil (UFBa), and from the Brazilian Ministry of Health through the Fundacao Oswaldo Cruz (FOC) and the Companhas de Saude Publica (SUCAM). The program is sponsored by the Pan American Health Organization (PAHO). Since 1972, three core facilities have been developed: (a) a base laboratory at the medical school in Salvador; (b) clinical resources on the medical wards of the Hospital Professor Edgard Santos; and (c) a censused, studied population in Castro Alves, a rural area 4 hours drive from Salvador, where prevalence rates for schistosomiasis and for Chagas' disease range from 50 to 90%. The program was initiated with a long-term grant from the Wellcome Trust, and by short-term grants from the Clark Foundation and from PAHO, support shortly to expire; the Wellcome Trust support will cease in 1980.

Research in progress on Chagas' disease includes: (a) Elucidation of specific morbidity and mortality by repetitive examinations of a defined population at 3 year intervals; (b) Comparison of value of Holter ambulatory electrocardiographic monitoring with standard techniques for characterization of arrhythmias in chronic Chagas' disease; (c) Investigation of the dynamics of transmission in 3 rural areas; (d) Exploration of possible cellular immunologic deficiencies in persistent infections; (e) Study of the role of immunopathologic mechanisms in pathogenesis.

Research in progress on schistosomiasis includes: (a) Follow-up of mass chemotherapy with respect to changes in morbidity; alteration in patterns of transmission and in serodiagnostic reactions; (b) Identification of environmental and social factors influencing transmission; (c) Detailed studies on the dynamics of vector snail populations.

IMMUNOBIOLOGY AND EPIDEMIOLOGY OF LEPROSY

K.E. Nelson, University of Illinois, Medical Center at Chicago, Peoria School of Medicine, Dept. of Preventive Medicine & Community Health, *1400 W. Main St., Peoria, Illinois* 60606 (P01 AI 16308-01)

This US-Thai collaborative program is designed to provide epidemiologic and immunologic information required for improved prevention or treatment of leprosy, and to provide better pharmacologic data for the use of common drugs in tropical areas of the world. The program is built upon the long-standing collaboration between the faculties of The University of Illinois College of Medicine and Chiang Mai University in northern Thailand. The Illinois core facility is the US center and includes laboratories for training Thai workers for work to be done in Thailand. The Chiang Mai core is the Thai laboratory and clinical facility. McKean Rehabilitation Institute, Chiang Mai, will provide access to 300 leprosy inpatients and 2000 outpatients through its associated villages and clinics. The component projects will investigate leprosy from epidemilogic, genetic, and immunologic viewpoints. M. leprae specific and nonspecific antibody, lymphocyte, and phagocytic cell responses will be characterized using techniques from the Universtity of Kentucky, and the University of Illinois. Studies of the role of immune complexes in leprosy and its complications including glomerulonephritis and erythema nodosum leprosum will be based at the University of New Mexico.

All component projects involve Thai co-investigators who, after training in the US, will implement the research in Thailand.

EPIDEMIOLOGY OF INFANT BOTULISM

J. Chin, State Dept. of Health, Infectious Disease Section, *2151 Berkeley Way, Berkeley, California* 94704 (R01 AI 16354-01)

The objective of this proposal is to determine the epidemiology of infant botulism, and to develop a profile of the high-risk infant.

The spectrum of severity of this disease is now known to range from mild outpatient illness to fulminant, unexpected death that at autopsy is indistinguishable from Sudden Infant Death Syndrome (SIDS). In order to identify mild cases, active surveillance will be used in addition to the surveillance systems used to identify hospitalized and fulminant (SIDS) cases.

These objectives will be accomplished by means of a longitudinal case-control epidemiologic and laboratory study.

ST LOUIS ENCEPHALITIS VIRUS IN TROPICAL ECOSYSTEMS

P. Galindo, Gorgas Memorial Inst. of Tropical & Preventive Medicine Inc., Gorgas Memorial Laboratory, *2007 I St. N.W., Washington, District of Columbia* 20006 (R01 AI 16433-01)

This project has been designed to elucidate the mechanisms by which St. Louis Encephalitis (SLE) virus cycles in tropical ecosystems, and to compare the biological characteristics of SLE strains representing different survival mechanisms of the virus in Panama an in the U.S.A., so as to assess possibilities of periodic introduction of the virus into the U.S.A. from the neotropics with the occurrence of urban epidemics and vice versa. A close monitoring for SLE activity will be maintained at three or more distinct tropical ecosystems where the virus previously was isolated. Dynamics of transmission will be studied by virus isolation from mosquitoes with determination of vectorial capacity of mosquitoes, including transovarial transmission and host preference. Viremia patterns of suspected vertebrates will also be studied. Characterization of SLE strains will be done at Yale University.

INTERNATIONAL RESEARCH IN INFECTIOUS DISEASES

T.C. Orihel, Tulane University of Louisiana, School of Public Health & Tropical Medicine, Dept. of Tropical Medicine, *6823 St. Charles Ave., New Orleans, Louisiana* 70118 (P01 AI 16315-01)

The primary objective of the proposed Tulane ICIDR is to develop research program in Colombia, South America, with headquarters in Cali, which will address major public health problems of the country, the neotropical region and the hemisphere, and which will be of interest and importance to the scientific community in other parts of the world. The research will be carried out as a collaborative effort between Colombian and American scientists on a broad interdisciplinary base and will focus primarily on parasitic diseases of man and, in certain instances, on related immunological problems. The major effort will be directed toward basic biological and epidemiological investigations of selected vector-borne, parasitic diseases of man including filariasis, leishmaniasis, trypanosomiasis and malaria. In connection with some of these activities, integrated studies on the vectors and vector-parasite relationships will be carried out. Parasitic diseases of the upper gastrointestinal tract namely, giardiasis and strongyloidiasis will be investigated with emphasis on the physiological environment in the gut which may favor the colonization by the parasites and produce symptomatic disease. Infectious diseases in pediatric populations of Colombia and the various factors which mediate the immune responses of children to infections represent other areas of special interest to the program. The Colombian Fund for Scientific Research (COLCIENCIAS) is the Colombian host and counterpart organization of the Tulane program. The program is open to Colombian scientists and institutions from throughout the country.

THE EPIDEMIOLOGY OF HUMAN INFECTIONS OF SPECIAL INTEREST

R.N. Philip, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Allergy & Infectious Diseases, Epidemiology Branch, *Hamilton, Montana* 59840 (Z01 AI 00081-18 EB)

This project emphasizes epidemiologic investigations of infectious diseases of particular interest to the research program of this laboratory. Current investigations include studies of the etiologic relationship of various spotted fever-group serotypes to human illness, and improvement in laboratory methods for diagnosis of rickettsial infections, particularly Rocky Mountain spotted fever.

LABORATORY AND EPIDEMIOLOGIC STUDIES OF VIRAL HEPATITIS AGENTS

R.H. Purcell, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Allergy & Infectious Diseases, Hepatitis Viruses Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 AI 00026-12 LID)

This project consists of continuing studies of the chemistry, structure, epidemiology, immunology and pathology of the human hepatitis viruses. The goal of such studies is the control of human viral hepatitis by application of the most appropriate methods, including active and passive immunization, chemotherapy and interdiction of spread of the viruses.

PROGRESS: Partial biophysical and biochemical characterization of hepatitis A virus has been achieved and studies of hepatitis type A in non-human primates, using defined pools of virus, are almost complete. There is preliminary evidence for successful cultivation of hepatitis virus in vitro. An inactivated subunit vaccine for hepatitis type B has been developed and is undergoing extensive tests of safety and efficacy in man. A third hepatitis B antigen, e antigen, is being characterized and its relationship to infectivity is being explored. Evidence that populations of hepatitis B viruses may contain defective interfering particles has been obtained, and this finding is being utilized in renewed attempts to isolate the virus. A newly recognized clinical syndrome, type non-A, non-B hepatitis has been further defined and attempts to identify an etiologic agent intensified through transmission studies in chimpanzees.

BASIC STUDIES ON MYCOPLASMAS

J.G. Tully, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Allergy & Infectious Diseases, Mycoplasma Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 AI 00027-12 LID)

These efforts cover both basic and applied aspects of mycoplasmas and related wall-free prokaryotes, including their neurotoxins, antigens and other biological factors involved in virulence, their immunological interrelationships, and their possible role in human disease or disease of uncertain etiology. Current projects of interest concern the characterization and serological interrelationships of an expanding group of helical mycoplasmas (spiroplasmas) being isolated from plants and a variety of insects, especially ticks. Recent studies have confirmed that many of these new organisms possess overt pathogenicity for vertebrates (embryonated chicken eggs and suckling rats), suggesting that they may represent important pathogens for man. Further sero-epidemiological studies in many seem warranted. Recent collaborative studies on the acholeplasmas (non-sterol-requiring mycoplasmas) isolated from plant and animal sources suggest some alteration in the concept that these organisms are parasitic. The occurrence of free-living acholeplasmas in plants, some species of which had previously only been found in vertebrates, raises important questions about vector transmission and other host-parasite relationships of these organisms.

SYSTEMATICS AND VECTOR RELATIONSHIPS OF CERTAIN PARASITIC ARTHROPODS

C.M. Clifford, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Allergy & Infectious Diseases, Arthropod Borne Diseases Section, *Hamilton, Montana* 59840 (Z01 AI 00069-48 EB)

The activities of this project currently comprise four main functions: 1) Identification of ticks received from various individuals and government agencies throughout the world. Only one other institution in the world is capable of performing this service. 2) Systematic study of certain groups of parasitic arthropods. The foremost tool in systematic studies, the scanning electron microscope, has greatly aided in elucidating toxonomic concepts in acarines actually or potentially involved in transmission of disease agents. 3) Final editing and storage of all RML and NAMRU-3 (Cairo) tick data in the Smithsonian data retrieval system. 4) Colonization of medically important arthropod vectors, which are furnished to outside investigators.

NATURAL HISTORY OF TICK-BORNE RICKETTSIAL AGENTS AND THEIR PUBLIC HEALTH SIGNIFICANCE

W. Burgdorfer, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Allergy & Infectious Diseases, Arthropod Borne Diseases Section, *Hamilton, Montana* 59840 (Z01 AI 00061-17 EB)

This project is concerned with studies of Rocky Mountain spotted fever and other tick-borne rickettsial diseases in the United States and other countries regarding ecology, identification, and characterization of the rickettsial agent(s) with their associated vectors. With collaboration of outside agencies (state health departments, public health laboratories, hospitals, physicians, etc.) source material for comparative studies on the various rickettsial types and information about the distribution of vector species associated with spotted fever in the United States is obtained. This project also considers the cellular and subcellular aspects of interaction between tick-borne agents, particularly rickettsiae, and their vectors.

CLINICAL EPIDEMIOLOGY - PATHOGENESIS OF GENITAL HERPES

L. Corey, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105 (R01 AI 14495-03)

We propose to test our current hypotheses concerning HVH latency and recurrence in humans and as secondary objective further prospectively describe the clinical epidemioloy of genital HVH. Among patients with primary genital HVH only 30% subsequently recrudesced contrasted with 60% recrudescence in HVH-2 patients. We plan to recruit and follow additional primary disease patients to expand our data base and to determine the effects of covariable also associated with recrudescence, race, age, age of acquisition of disease, sexual behavior, and mediated immunity. We have also seen that only 10% of primary HVH-1 patients had detectable anti-HVH antibody compared to 93% of primary HVH-2 patients. We wish to see if preexisting anti-HVH antibody protects against type 1 or 2 clinical disease and to examine other variables which may interact to influence this. Lastly we plan to test the hypothesis that recurrent genital herpes depends upon a mechanism of antigenic draft. We will look for subtle antigenic differences using serial isolates from individual patients, serial sera from patients and rabbit anti-HVH raised against specific serial isolates.

NOSOCOMIAL INFECTION IN SURGICAL PATIENTS

R.A. Garibaldi, Utah Higher Education System, University of Utah, School of Medicine, Dept. of Internal Medicine, *1400 E. 2nd S., Salt Lake City, Utah* 84112 (R01 AI 14533-02)

We are studying the pathogenesis and epidemiology of post-operative infections to develop more effective approaches for their prevention and control. We have designed a new method for obtaining quantitative wound cultures using a micropore filter mounted on a nutritive agar media; this technique is more than two times as sesitive as presently available quantitative culture techniques. With this technique, we are analyzing factors which may predispose to or prevent intraoperative colonization of surgical wounds in an effectiveness of pre-operative and intra-operative interventions attempting to decrease bacterial contamination of the wound and subsequent infection.

We have begun a series of clinical studies designed to assess the efficacy of certain, previously unproven practices which have been advocated to reduce post-operative infection rates. We have shown that bacterial gas filters on inhalation anesthesia circuitary has no effect in preventing post-operative pulmonary infections. Previously, the use of such filters had been widely accepted without any clinical proof of efficacy. In addition, we have determined infection risks and calculated infection costs for a variety of surgical procedures: these data will help us to perform cost/benefit analyses of other, more efficacious preventive approaches.

LYMPHOCYTOTOXIC ANTIBODY AND IMMUNE REGULATION IN SLE

R.J. De Horatius, Thomas Jefferson University, Jefferson Medical College, Dept. of Medicine, *1025 Walnut St., Philadelphia, Pennsylvania* 19107 (R23 AI 14574-02)

Family studies of patients with systemic lupus erythematosus have shown an increased incidence of many autoantibodies. This has included lymphocytotoxic antibody and antibodies to nucleic acids. The proposed research project will examine the function of these antibodies on several parameters of immune regulation in the family members of patients with systemic lupus erythematosus. This will utilize in vitro studies of mixed lymphocyte reactivity, HLA determination, and lymphocytotoxic antibody assays. Comprehensive family studies and studies of human household contacts of dogs with lupus will allow determinations of the role played by environmental and genetic influences on the development of overt disease in SLE patients. These results will be analyzed with respect to other known genetic markers such as ABO and Rh blood typings. Attempts will be made to define the specificity of the lymphocytotoxic antibody with respect to the antigen against which it is determined. This will utilize lymphocytes from patients with other diseases shown in previous studies to have lymphocytotoxic antibody. This will be performed by means of appropriate absorption studies prior to the assay for lymphocytotoxic antibody.

TRANSMISSION AND CONTROL OF CALIFORNIA-GROUP VIRUSES

G.R. DeFoliart, University of Wisconsin, Madison Campus, School of Agriculture & Life Sciences, Dept. of Entomology, *Agriculture Hall, Madison, Wisconsin* 53706 (R01 AI 07453-14)

Recent findings, notably that Aedes triseriatus mosquitoes orally infected with La Crosse (LAC) virus do not produce transovarially infected progeny until the second oviposition following the infectious bloodmeal, have made it mandatory to determine survivorship to the 2nd and subsequent ovipositions in order to assess the significance of horizontal amplification via vertebrates in endemic survival of the virus. Efforts will focus, therefore, on the development of trapping techniques to be used in estimating mosquito survival to mating, the first and subsequent ovipositions and the first and subsequent bloodmeals.

The circumstances of human infection with LAC virus under urban and semi-urban conditions will also be investigated. Preiminary evidence indicates that a high proportion of human California encephalitis cases result from contact with Aedes triseriatus mosquitoes bred in discarded tires and other man-made containers.

PHILIPPINE SCHISTOSOMIASIS JAPONICA:

R.M. Lewert, University of Chicago, School of Medicine, Dept. of Microbiology, *5801 S. Ellis Ave., Chicago, Illinois* 60637 (R22 AI 07724-12S1)

The objectives of this project broadly stated are to conduct complementary field and laboratory investigations of Schistosoma japonicum infections with emphasis on immune phenomena which might be correlated with clinical disease states. We propose to monitor anti-body and cell mediated immune response including possibly significant associated phenomena in selected population groups living in an area where Schistosoma japonicum is highly endemic. Attempts will be made to correlate these observations with parasitologic and clinical data, with notes of fluctuation or changes over a five year period, and to assess if possible the degree to which the immune phenomena contribute directly to the pathology of the disease. The role of immune renal pathology, autoimmune reactions, antiglobulin antibody and cryoglobulins will be examined. These studies are being carried out as a cooperative program with the Phillipine Department of Health with field studies on Samar and Leyte, The Phillipines.

TOXOPLASMOSIS - NATURE OF INFECTION & IMMUNE RESPONSE

J.S. Remington, Palo Alto Medical Research Foundation, Division of Allergy Immunology & Infectious Diseases, *860 Bryant St., Palo Alto, California* 94301 (R01 AI 04717-19)

The results of the proposed studies will provide a better understanding of the biology and immunology of Toxoplasma gondii and the epidemiology, diagnosis and treatment of acute and chronic congenital and acquired toxoplasmosis, and the unique role of Toxoplasma in infection in the immunologically compromised host. Genetic variation and virulence of cloned 'strains' of Toxoplasma will be studied and comparisons will be made of the antigenic structure of Toxoplasma to related and unrelated protozoa. Prospective studies of the incidence of congenital toxoplasmosis will be carried out by studying seroconversion during pregnancy. Prospective, as well as retrospective, studies of the incidence of retinochoroiditis in acquired infection will also be made. Presently available diagnostic procedures will be improved and new ones developed, including a radioimmunoassay for circulating antigen, increasing the sensitivity of the IgM-IFA test, determining the

feasibility of demonstrating Toxoplasma in brain biopsy material, and further characterization of the histopathology of the lymphadenopathic form. The site of circulating Toxoplasma in patients with parasitemia will be determined and the dynamics of endogenous reinfection will be studied in the normal and immunosuppressed host. The role of the lymphocyte-macrophage system in resistance to Toxoplasma will be studied, including: the nature of the lymphocyte response to Toxoplasma, suppression of specific lymphocyte recognition of Toxoplasma and activation of macrophages during acute human toxoplasmosis, the specificity of macrophage recognition of Toxoplasma, and the role of alveolar macrophages in resistance to Toxoplasma. The efficacy of newer antimicrobials and their synergistic effects will be evaluated in animal models.

HABITAT & TRANSMISSION OF PNEUMOCYSTIS CARINII

W.T. Hughes, Johns Hopkins University, School of Medicine, Dept. of Pediatrics, *725 N. Wolfe St., Baltimore, Maryland* 21205 (R01 AI 14769-03)

The objective of the research is to learn the mode of transmission and natural habitat of P. carinii. Prerequisite to these studies is the need for a susceptible P. carinii-free animal model to serve as a host under experimental challenges. We have been successful in developing such a model with CD axenic weanling germ-free rats maintained in a Hoeltge isolator and given sterile prednisone orally.

Because of morphologic, tinctorial and immunologic similarities of two algae, Prototheca and Chlorella, sp. these were investigated for their potential to cause disease in animals. Both of these organisms caused deep-organ infections in immunosuppressed rats.

STUDY OF A NEW HUMAN PAPOVAVIRUS

D.L. Walker, University of Wisconsin, Madison Campus, Medical School, Dept. of Medical Microbiology ::, *307 N. Charles St., Madison, Wisconsin* 53706 (R01 AI 11217-07)

Proposed work includes: 1. Efforts to cultivate JC virus in cells other than human fetal glial cells. 2. Continued studies of the role of JC virus, and to a lesser extent BK virus, in human infections and disease. Much of the work will be concentrated on the epidemiology of JC virus and BK virus and on JC virus in progressive multifocal leukoencephalopathy. 3. Study of the oncogenicity of JC virus, particularly in primates.

HUMORAL, CELLULAR & GENETIC MECHANISMS IN AUTOIMMUNITY

H.O. McDevitt, Stanford University, School of Medicine, Dept. of Medicine, *Stanford, California* 94305 (P01 AI 11313-07)

The objective of the research proposal is to study mechanisms of immunogenetics, autoimmunity and immunosuppression in order to translate experimental findings and concepts of basic and clinical immunology into knowledge which is useful for the diagnosis and treatment of human disease. New cell surface antigens coded for by the major histocompatibility complex (MHC) in man will be defined, and their association with specific rheumatic and autoimmune diseases will be studied. The immune response of HLA-B27 positive and negative individuals to purified antigens from strains of Shigella which do and do not cause Reiter's syndrome will be studied. Patterns of autoantibodies and clinical presentation will be investigated in the rheumatic diseases in order to further classify subtypes of disease. Finally, a new modality of immunosuppression, fractionated total lymphoid irradiation, will be studied for efficacy in the treatment of rheumatoid arthritis, autoimmune diseases of laboratory rodents, and rejection of allogeneic bone marrow transplants in dogs.

LA CROSSE ARBOVIRUS STUDIES IN FORESTED AREAS

W.H. Thompson, University of Wisconsin, Madison Campus, Medical School, Dept. of Preventive Medicine, *307 N. Charles St., Madison, Wisconsin* 53706 (R01 AI 11547-07)

The natural maintenance cycle of LAC virus in forested areas will be studied in field and laboratory research focused on mechanisms and relative importance of vertical (transvarial) and horizontal (venereal and salivary transfer through mammals) transmission of virus.

Data on isolates from the mosquito vector and antibody rates in chipmunks and squirrels obtained from studies in an endemic area in suburban La Crosse will be compared with those obtained from the edge of this endemic area in central Wisconsin and from islands of LAC activity as recently located in a highly-populated suburban area near Milwaukee in eastern Wisconsin.

Selected cases of California encephalitis, occurring each year in Wisconsin and other midwestern states, will be studied for distribution and circumstances of infection. Results of epidemiologic surveys to be conducted in residents of the newly found isolated area of LAC virus in highly-populated eastern Wisconsin will be compared with results recently obtained in residents in the endemic area.

Enhancement of venereal infection and transovarial and salivary transmission rates, so far observed with LAC virus in colonized female Aedes triseriatus given blood-meals before mating, will be further studied with naturally infected females and F1 progeny.

VENEREAL DISEASE RESEARCH PROGRAM PROJECT

K.K. Holmes, University of Washington, School of Medicine, Dept. of Medicine, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (P01 AI 12192-05)

This program project has research components: I. Clinical Epidemiology and Pathogenesis of Gonococcal Infections: Methods include auxo-typing, outer membrane protein typing, and fluorescent antibody typing, phagocytosis of gonococci by human polymorphonuclear leukocytes, and use of antigen-specific opsonizing antibody and bactericidal antibody. II. Genetic Studies of Neisseria gonorrhoeae: The general purpose of the proposed research is to study the genetic organization of the gonococcus, Neisseria gonorrhoeae, as well as other microorganisms that cause significant sexually transmitted diseases. The thrust of our research is aimed at recognizing the nature of the determinants that contribute to bacterial virulence. By using classical genetic methods coupled with the newer techniques of recombinant DNA research we have been characterizing the pili genes of the gonococcus. We hope to better understand the precise role by which pili permit gonococci to attach to epithelial cells of susceptible tissues. In another vein, we have shown that a plasmid species is common to all strains of chlamydia. It is possible that this plasmid encodes for a polypeptide important in the pathogenesis of chlamydial disease. III. Nonogonoccal Urethritis and Related Infections: The etiology of chlamydia-negative nongonococcal urethritis, and the clinical spectrum and immunology of chlamydia trachomatis infectons are being studied. IV. Treatment and Pathogenesis of Hemophilus vaginalis Infection: The role of H. vaginalis and anaerobic bacteria in the etiology and pathogenesis of nonspecific vaginitis, and the optimal methods for therapy of this infection are being studied.

EVOLUTION AND EPIDEMIOLOGY OF ANTIBIOTIC RESISTANCE

R.H. Olsen, University of Michigan, Ann Arbor Campus, Medical School, Dept. of Microbiology, *1335 E. Catherine St., Ann Arbor, Michigan* 48104 (R01 AI 14880-03)

We will determine the basis, at the molecular level, for the apparent limitation of R-plasmid bacterial host range among hospital bacteria. Preliminary experiments indicate the presence of a migrating controlling DNA sequence analagous to that proposed for higher life-forms. This element will be further characterized by genetic and molecular parameters. The verification of the modus operandi of the proposed controlling element has important implications to the understanding of the epidemiology of infectious antibiotic resistance among Gram-negative bacteria common to the hospital environment.

NORTH CAROLINA PROGRAM ON SEXUALLY TRANSMITTED DISEASE

P.F. Sparling, University of North Carolina, Chapel Hill Campus, School of Medicine, Dept. of Medicine, *Manning Dr., Chapel Hill, North Carolina* 27514 (P01 AI 15036-02)

This is a multidisciplinary program project, with research activities in the areas of gonorrhea and syphilis. Emphasis is on both basic microbiology and immunology, and applied problems such as organism identification and clinical epidemiology.

Four integrated projects focus on the gonococcus, including basic genetics, biochemistry and antigenicity of the cell surface; virulence and host immune response; and importance of cell-wall deficient forms in human disease. Two integrated projects examine the basic physiology, pathogenicity, and immunology of T. pallidum.

ORIGIN OF PANDEMIC INFLUENZA VIRUSES

R.G. Webster, St. Jude Childrens Research Hospital, Division of Virology, *332 N. Lauderdale St., P.O. Box 318, Memphis, Tennessee* 38101 (R01 AI 08831-12)

The long-term objective of the proposed study is to elucidate the mechanisms of variation in influenza A

and B viruses. This includes both antigenic variation and variation in the other six gene products of influenza viruses. The objectives and methods are: 1) To prepare monoclonal antibodies to each of the gene products of the reference strains of H1N1, H3N2, and influenza B viruses. 2) To utilize monoclonal antibodies to determine the number and location of the antigenic determinants on the hemagglutinin and neuraminidase molecules of these viruses and to relate them to the primary structure of the molecules. The number of determinants will be established with monoclonal antibodies in serological assays. Antigenic variants will be selected, the surface proteins will be peptide mapped and variant peptides related to the primary amino acid sequence. The location of the antigenic determinants on the molecules will be determined by X-ray crystalography. 3) To characterize the gene product of influenza viruses with monoclonal antibodies and determine what constitutes an epidemiologically important strain using serological assays and RNA hybridization. 4) To establish the gene constellations of avian and mammalian influenza viruses that control tissue tropism and host range using recombinants between avian strains of influenza virus that replicate in the cells lining the intestinal tract of ducks and humans strain that do not replicate in ducks. 5) To elucidate the role of the different determinants on the gene products of influenza virus in antibody- and cell-mediated immunity using monoclonal antibodies in in vivo and in vitro assays.

SUPPORT FOR INTERNATIONAL CENTER FOR MEDICAL RESEARCH

R.B. Sack, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Medicine, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R07 AI 10048-19)

Research will continue to be focused on the clinical and epidemiological aspects of acute diarrheal disease of children and adults. This work will now be done entirely in Panama, in collaboration with the Gorgas Memorial Laboratories, and other local Panamanian Institutions. The work will include a) epidemiologic studies of acute diarrhea in children seen at the Gorgas Hospital and at the Curcundu Urban Health Clinic, b) diarrheal surveillance in several well-defined rural Indian populations in Panama, and c) a controlled clinical study comparing two oral glucose-electrolyte solutions (50 or 90 mEq sodium/L) in the therapy of small children hospitalized with acute diarrheal diseases.

SUPPORT FOR INTERNATIONAL CENTER FOR MEDICAL RESEARCH

A. Rudnick, University of California, San Francisco Campus, School of Medicine, Dept. of International Health, *551 Parnassus Ave., San Francisco, California* 94122 (R07 AI 10051-18)

The University of California International Center for Medical Research is devoted to (a) the promotion of research in international health, with emphasis on problems in Malaysia and the nearby Western Pacific and Southeast Asis; (b) furthering application of this reseach to domestic health problems in the United States; and (c) providing research opportunities for scientists in international health and related desciplines in a tropical environment. The Center staff comprises a few longterm scientists and a varying number of short-term scientists, usually on 2-year assignments.

Currrent research interests include Arbovirology (including medical entomology); Community Health (medical behavioral research with special reference to parasitism and infection, traditional medical systems and health in changing environments); Human Genetics (abnormal red cell metabolism, genetic traits in relation to disease and infection, and population genetics); Parasitology (emphasizing biological control of trematodes and snail immunity).

ALLERGENICITY OF AIRBORNE PARTICULATES

W.R. Solomon, University of Michigan, Ann Arbor Campus, Medical School, Dept. of Internal Medicine, *1335 E. Catherine St., Ann Arbor, Michigan* 48104 (R01 AI 10181-09)

The proposed studies will extend ongoing investigations of the potential, as human allergens, of a variety of airborne biological particles of demonstrated abundance. Specifically, spores of select ascomycetes, basidiomycetes and myxomycetes will be obtained from field sources or, rarely, laboratory culture and extracted to provide material for kin and mucosal testing of selected atopic subjects. Comparative allergenic properties of distinct 'form species' of imperfect fungi will be assayed similarly and studied by the use of immunoadsorbents. Optimal methods for preparation of fungus extracts for clinical use will be sought and media for recovery of fungi from air compared critically. Present studies of the fungus flora of homes will be extended to survey possible actinomycete contamination and the role of humidifying equipment as a dominant source of microbial aerosols will be evaluated. Window air conditioning units will be studied, both as a means of excluding extramural aeroallergens and as a potential source of these agents. The possible occurrence of pollen allergens in association with aerosol fractions below 10 micra in equivalent diameter will also be sought.

EPIDEMIOLOGY OF ECHINOCOCCOSIS

F.L. Andersen, Brigham Young University, Center for Health & Environmental Studies, Dept. of Zoology, *115 Page, Provo, Utah* 84602 (R01 AI 10588-09)

Hydatid disease is now known to be endemic in two regions of Utah and in a few isolated areas of neighboring states, such as the Navajo and Zuni Indian Reservations. Our project is a continued effort to identify important factors in the epidemiology of the disease and measures which can feasibly be implemented in preventive and control programs within this geographical area.

Studies proposed for the coming year include: (1) surveillance of sheep and dogs for Echinococcus granulosus in attempts to monitor the situation in known endemic regions and identify any new foci of infections, (2) develop an educational coloring book on hydatid disease for residents of central Utah and for Zuni Indians, (3) conduct and analyze additional attitudinal surveys on hydatid disease, (4) evaluate chemotherapeutic agents on E. multilocularis in cats and rodents, and (5) conduct electron microscope studies on E. granulosus, E. multilocularis, and Taenia hydatigena.

BIBLIOGRAPHIC REFERENCES: Andersen, F. L., G. A. Conder, and W. P. Marsland: Efficacy of injectable and tablet formulations of praziquantel against mature Echinococcus granulosus. Am. J. Vet. HEPATITIS, HAA, AND ANTI-HAA IN MOTHERS AND INFANTS

M.J. Tong, University of Southern California, School of Medicine, Dept. of Medicine, *2025 Zonal Ave., Los Angeles, California* 90033 (R01 AI 10894-07A1)

The research objectives of this study are to determine the efficacy of hepatitis B immune globulin (HBIG) in altering the incidence of hepatitis B virus (HBV) infection in infants born 1) to mothers with acute hepatitis B during the 3rd trimester of pregnancy and immediate 2-month postpartum period, and 2) to asymptomatic HBsAg carrier mothers. Infants born to mothers with acute type B hepatitis during the delivery period will receive one injection of HBIG within 2 weeks of delivery. All infants will be followed on a monthly basis and tested for evidence of HBV infection. These results will be compared to the 70% HBsAg positivity which we found in infants born to mothers with acute hepatitis B during the past 6 years (historical controls). Infants born to HBsAg carrier mothers will be divided into 2 groups according to the maternal HBeAg test. Those born to HBeAg mothers will be randomized in a double blind fashion for HBIG or saline placebo treatment. Infants born to HBeAg negative carrier mothers will be similarly randomized. Each infant will be treated within 2 weeks of delivery, and at 4, 8, and 12 months of age. All infants will be followed monthly for evidence of HBV infection. Also, we will follow the children who have been found to be persistently HBsAg during the course of this study. This includes clinical evaluation, tests of liver function, HBsAg titers, HBeAg, anti-HBe, DNA polymerase and anti-HBc measurements on a regular basis. If deemed necessary, further clinical studies will be performed to determine the type and extent of the liver disease which may develop. long term followup is required to elucidate the natural course of the hepatitis B infection in these infants. We are also studying the incidence of HBsAg infection in 1) family members of HBsAg carrier mothers and 2) family members of the persistently HBsAg positive infants. If HBsAg, then other studies will be performed to determine the type and severity of liver disease in these individuals. With he availability of the immune adherence test for hepatitis A (HA), we plan to study the incidence of type A hepatitis in pregnant females, and look for the presence of anti-HA in the cord blood and newborn infants. Hepatitis A infection will also be studied in the neonates with serial clinical, biochemical and serologic studies.

SUPPORT FOR WORLD REFERENCE CENTER FOR ARBOVIRUSES

J. Casalsariet, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Ceciar St., New Haven, Connecticut* 06510 (R01 AI 10984-08)

The World Reference Center for Arboviruses identifies and characterizes viruses suspected of being biologically transmitted by arthropods as well as certain other viruses similar in some respects to arboviruses. A collection of about 450 already characterized reference viruses and immune sera and ascitic fluids is utilized in neutralization, complement-fixation, hemagglutination-inhibition and immunofluorescence tests to determine the relationship of referred viruses to the reference viruses. Physical and morphological characteristics of selected new arboviruses are determined by electron microscopy and polyacrylamide gel electrophoresis. The collection is also used for serologic diagnosis of disease, study of epidemics and seroepidemiologic surveys. This collection of reference arboviruses is the only complete collection in the world. The long-term aim is to develop new research areas and research models in virology and epidemiology as has been done in the past with Congo-Crimean hemorrhagic fever and Lassa fever viruses, rabies-related viruses, tick-borne orbiviruses of Ixodes uriae, insect viruses (Baculoviruses) and the use of insect cell cultures.

BIBLIOGRAPHIC REFERENCES: Casals, J., Togavirus: Alphavirus, and Togavirus: Flavivirus, In 'CRC Handbook Series of Clinical Laboratory Science', Hsiung, G.D., and Green, R.N., eds., CRC Press Inc., in press, 1978. DETERMINANTS OF VIRULENCE IN BACTEROIDES FRAGILIS

F.P. Tally, New England Medical Center Hospital, Infectious Disease Section, *171 Harrison Ave., Boston, Massachusetts* 02111 (R01 AI 15389-01A1)

The significant role that anaerobic bacteria play in suppurative infection in man has beeen firmly established. Among all the anaerobic species, Bacteroides

fragilis stands out as the most importnat pathogen because of its frequency of isolation and resistance to many antimicrobial agents. Despite the voluminous literature on B. fragilis, little is known about its pathogenic mechanisms. Current research on virulence factors have been hampered by an inability to distinguish strain differences within B. fragilis and by the lack of a genetic system. Recent studies have provided the genetic tools to facilitate systematic invesigation of potential virulence factors in B. fragilis. The objective of this proposal is to apply the techniques of molecular biology employed for the study of aerobic organisms to define the determinants of virulence in B. fragilis. The isolates selected for study will fit the phenotype description of the type strain of B. fragilis. Transferable drug resistance will be further characterized by studying the 2 megadalton clindamycin resistance plasmid and the larger transfer factor. A transformation system will be developed utilizing the clindamycin plasmid. Characteristics which have been suggested as virulence factors will be studied by obtaining derivatives of pathogenic strains lacking the attribute and testing these clones in a rat model of intraabdominal sepsis. Initial phenotypic characteristics to be studied are the polysaccharide capsule, superoxide dismutase, catalase, extracellular nucleases and lipases. Finally, the epidemiology of B. fragilis infections will be defined using the technique of phage typing. Virulent bacteriophage of B. fragilis will be utilized to develop the typing system to determine if there are specific species associated with infections in different parts of the country and with specific sites in the body. Phage types in the normal flora will be examined. The effect that hospitalization and preoperative antibiotics have on phage types will be studied. These studies will give some insight on whether B. fragilis infections are endogenous or nosocomial.

2.0921,

EPIDEMIOLOGY OF INFECTION WITH ATYPICAL MYCOBACTERIA

H. Gruft, State Div. of Lab. & Research, *Empire State Plaza, Albany, New York* 12237 (R22 AI 13813-04)

Persons infected by Mycobacterium intracellulare, as demonstrated by positive skin test to the antigen, are concentrated in the southeastern coastal area of the United States. This geographical distribution is unlike that of persons exposed to M. tuberculosis and provides a hypothesis to the possible source of infection with M. intracellulare and other atypical Mycobacteria. Our research proposed to continue testing the hypothesis that the source of the infection is Mycobacteria residing in either the estuaries or fresh water of the southeastern United States or animals (birds especially) that are associated with these habitats. These Mycobacteria are concentrated at the surface of bubbles formed during wave action and rain or spread in dusts. The experimental approach involves sampling air as well as surface and subsurface waters and soils in various areas of the southeastern United States, at and off the coast of Virginia, South Carolina, Maryland, etc. Initial studies by the principal investigators have already demonstrated the effectiveness of this approach. The concentration of Mycobacteria, their frequency of isolation, and identification of each isolate will be part of this study. The data concentration and frequency of isolation, and identification of each isolate will be part of this study. The data of concentration and frequency of isolation will be compared to samples from areas where the incidence of infection with M. intracellulare is lower (upstate New York and New England). In addition, the physiological ecology of these organisms is being investigated to determine the basis for the unique geographical distribution.

ECOLOGY OF PATHOGENIC VIBRIOS

R.R. Colwell, University of Maryland, College Park Campus, School of Agriculture, Dept. of Microbiology, *College Park, Maryland* 20742 (R22 AI 14242-03)

Studies on seasonal abundance and distribution of Vibrio and related species from a water supply in a cholera endemic area (Bangladesh) will be continued. Isolated strains will be subjected to extensive numerical analysis, examined for enteropathogenicity and antibiotic resistance patterns, and analyzed for presence of extrachromosomal genetic elements. The relationship of NAG strains of V. cholerae isolated from the water supply and from the Chesapeake Bay to classical and El Tor V. cholerae will be studied by systematic analysis and DNA/DNA hybridization studies. Analysis of enterotoxic factors of NAG vibrios, of V. parahaemolyticus and of Aeromonas hydrophila will be pursued on both ecological and molecular genetic bases. Correlations will be sought between individual strain characteristics and presence of extrachromosomal elements, and factors relating to pathogenicity and natural distribution. By using a computer based system, development of an online identification system for Vibrio species will be developed.

BIBLIOGRAPHIC REFERENCES: J. Kaper, H. Lockman, R.R. Colwell, and S.W. Joseph. 1979. Ecology, serology, and enterotoxin production of Vibrio cholerae in Chesapeake Bay. Appl. Environ. STUDIES OF INFECTIOUS DIARRHEAL DISEASES

N.F. Pierce, Johns Hopkins University, School of Medicine, Dept. of Medicine, *725 N. Wolfe St., Baltimore, Maryland* 21205 (P01 AI 14480-03)

This project focuses on the immunology, immunoprophylaxis, and microbiology of acute intestinal infections: viral, bacterial and parasitic. Antigens associated with gut flora appear to cause clonal expansion of antigen-sensitive cells of appropriate specificities in Peyer's patches and also drive the process of B-cell differentiation such that cells in Peyer's patches preferentially become committed to expression of IgA antibodies. Techniques for studying 'cross-priming' of mucosal surfaces by respiratory and enteric antigens have been developed. Protein deficiency has been shown to markedly impair a specific mucosal immune response to a protein antigen. The migrating patterns of IgA memory cells, antigen-specific suppressor cells and cells destined to produce specific IgA antibody after enteric immunization with cholera toxin have been partly determined. Cells conveying memory and suppression disseminate to distant mucosal surfaces whereas IgA plasmablasts home largely to the organ of origin. The DNA sequences for E. coli LT A- and B-subunits have been cloned separately and the recombinant plasmids are available for study. Efforts are underway to develop a more reliable adult animal model for toxigenic E. coli diarrhea so that E. coli strains which produce defective LT can be studied as possible live vaccines. Detailed studies of the viral nucleic acids and proteins of the SA-II and porcine rotaviruses are underway. Progress has been made in purification of the structural polypeptides of SA-II; the rates of synthesis of these and non-structural polypeptides in infected cells have been studied; a serodiagnostic facility to support clinical and epidemiologic studies of human rotavirus infections has been established.

BIBLIOGRAPHIC REFERENCES: Barry, W. S., Pierce, N. F. Protein deprivation causes reversible impairment of the mucosal immune response to cholera toxoid/toxin in rat gut. Nature 281:64-65, 1979. NATURAL HISTORY OF THE ORGANISM OF LEGIONNAIRES' DISEASE

S.M. Katz, Hahnemann Medical College & Hospital, School of Medicine, Dept. of Pathology & Laboratory Medicine, *235 N. 15th St., Philadelphia, Pennsylvania* 19102 (R01 AI 15593-01)

The objective is to characterize the natural history of the organism of Legionnaires' disease. Experiments, divided into three groups, will attempt to: a) Clarify the ecologic niche: We will investigate the morphology of the transition from intracellular to cell-free growth, and the potential of spore-like structures to germinate; b) Elucidate mode of transmission: By pathologic techniques, we will compare the pathology produced in guinea pigs by 3 routes of inoculation: air, water and intraperitoneal; c) Delineate pathology: By light, immunofluorescent and electron microscopy we will describe the pathology of Legionnaires' disease in guinea pigs and humans, including distribution and features of the organisms within lesions. We will attempt to develop a diagnostic test for the acute phase of the illness. Data from the experiments will be used to clarify the taxonomy of the organism.

CONTROL OF HOSPITAL-ACQUIRED URINARY TRACT INFECTIONS

J.P. Burke, Utah Higher Education System, University of Utah, LDS Hospital, *325 8th Ave., Salt Lake City, Utah* 84103 (R01 AI 15655-01)

These studies are designed to increase our understanding of the epidemiology, significance, pathogenesis, and control of nosocomial urinary tract infections in hospitalized patients who receive indwelling urethral catheters. In the past four years, we have established a program for the daily bacteriologic monitoring of urinary drainage systems and, using a unique computerized medical records system, developed techniques for implementing prospective, randomized, controlled studies of preventive methods.

In recent studies, we have identified bacterial colonization of the urethral meatuscatheter junction as an important risk factor for later bacteriuria, and demonstrated the failure of prevention using an iodophor disinfectant applied twice daily to the meatal surface. We will continue these studies by evaluating other topical antimicrobials for meatal care as well as other preventive approaches, such as the use of silicone catheters, weekly changes of catheters, and systemic treatment with trimethoprim-sulfamethoxazole.

We will continue our long-term epidemiologic studies of the incidence and associated risk factors for catheter-related gram-negative bacteremia. We propose to evaluate a test for antibody-coating of urinary bacteria as an epidemiologic tool to predict morbidity and persistance of bacteriuria.

We will utilize our monitoring system to develop techniques to eliminate unnecessary catheterization and to encourage early removal of catheters. The ultimate goal of our project is to develp practical methods for prevention and control of catheter-associated infections that can be used in all hospitals. Toward this end, we will implement and test suitable methods in a nearby private hospital that has not been the site of previous study.

EPIDEMIOLOGY OF THE GROUP B STREPTOCOCCUS

B.F. Anthony, University of California, Los Angeles Campus, Los Angeles County Harbor General Hospital, *1000 W. Carson St., Torrance, California* 90509 (R01 AI 15698-01)

Pregnant women and newborn infants will be followed to detect and measure group B streptococci, an important cause of newborn infections. The purpose is to understand the epidemiology and carriage of this bacterium, particularly with reference to the gastrointestinal tract. Healthy adult volunteers will be studied to locate the sites of streptococcal carriage in the gastrointestinal tract. Patients and their contacts will be studied in a veneral disease clinic to

evaluate the importance of sexual transmission in streptococcal spread.

PNEUMOCOCCAL VACCINE IN THE INSTITUTIONALIZED ELDERLY
D.W. Bentley, University of Rochester, School of Medicine & Dentistry, Dept. of Medicine, *601 Elmwood Ave., Rochester, New York* 14627 (R01 AI 15778-01)
To evaluate the current pneumococcal vaccine in the institutionalized elderly by observing vaccine-associated reactions and subsequent incidence and etiology of pneumonias and pneumonia-associated mortality.
We plan to study approximately 1,900 patients from 4 different chronic-care institutions. The study population will consist of approximately 700 patients who have been institutionalized for less than 400 days at the time of vaccination and additional 1,200 new admissions who will be entered over the next 12 months. These patients will be selected because they are at an especially high risk for acquiring pneumococcal pneumonia; they will be followed for 1-2 years (depending on their data of entry) or until discharge. Prior to vaccination extensive in-services will be performed to insure that all respiratory infections will be investigated by clinical examination, chest roentgenograms, and cultures of respiratory secretions and blood prior to starting antimicrobials. Special studies to identify and recover S. pneumoniae (pneumococcus) will include direct Quellung reaction with omniserum and counterimmunoelectrophoresis of respiratory secretions, selective-inhibitory media and typing of all isolates with Danish monovalent typing sera. Vaccinees will be observed for immediate-acute, local and constitutional reactions. This population will be exposed to approximately 700 patient years of risk per year of developing a pneumonia. Information will be obtained on the incidence of pneumonia, bacteremia, and mortality (total pneumococcal and pneumococcal due to sera types contained in the vaccine) per 1,000 patient years; the etiology of all radiologically confirmed pneumonias and the pneumoccal types associated with respiratory events, radiologically confirmed pneumonias and pneumonia-associated deaths. Surveillance figures collected at the Monroe Community Hospital for four years prior to vaccination will be used for comparison.

PSYCHOSOCIAL AND BIOCHEMICAL RISKS FOR MONONUCLEOSIS
E.G. Shaskan, University of Connecticut, Health Center, School of Medicine, Dept. of Psychiatry, *Farmington Ave., Farmington, Connecticut* 06032 (R01 AI 15901-02)
Psychosocial factors in the development of clinical illness have been extensively documented. It is probable that at least one mode of action of these factors is through modifying host-resistance as an outcome of central nervous system physiology, including hypothalamic neuroendocrine pathways. Since the disposition and metabolism of hypothalamic monoamines, especially dopamine, is reported to be intimately related to several hypothalamic releasing hormones, blood platelet monoamine oxidase (MAO) activity, as a genetically stable marker, is postulated to be a simple screening procedure for hypothalamic dopaminergic physiology. Perhaps psychosocial factors and platelet MAO activity can be ultimately synthesized in a multivariate equation, predicting risk for clinical symptoms of infectious mononucleosis (IM). Such risk for physical illness, when considering preliminary platelet MAO data alone, appears to be antithetically related to risk for certain psychiatric illnesses.
Following two successive years of preliminary, prospective studies of IM in college age students, a fully-prospective epidemiologic design has now been generated to include a variety of psychosocial instruments in addition to prospective evaluations of platelet MAO activity. Preliminary evidence to date identifies clinical IM as dependent upon brain and behavior. The existence of a fluorescent method for Epstein-Barr virus (EBV) antibody screening, utilized prospectively, is the principal serological basis upon which clinical IM and inapparent EBV infections are discriminated. Through such means of prospective discrimination, the psychosocial and biochemical risk factors are evaluated and synthesized within the broad interactive fields of modern medicine and psychiatry.

ENVIRONMENTAL-OCCUPATION HYPERSENSITIVITY CHEST DISEASE
J.E. Salvaggio, Tulane University of Louisiana, School of Medicine, Dept. of Medicine, *1430 Tulane Ave., New Orleans, Louisiana* 70112 (P50 AI 13401-05)
During the coming year we proposed to continue investigative pursuits in three areas. (1) Characterization of antigens and detection of specific antibody in coffee worker's asthma. (2) Induction of autoantibodies and the role of autoallergic factors in selected forms of occupational interstitial fibrosis (silicosis and asbestosis). (3) Preparation and characterization of antigens from different species of fungi which are abundant in the New Orleans environment and may be responsible for epidemics of asthma in this area of the country.
In our studies of coffee worker's asthma, we have begun to isolate and analyze allergens in green coffee and castor beans during the 01 year. Investigative studies of the biochemical and biological properties of these allergens will be pursued during the 02 years. With regard to our studies on autoantibodies in diffuse interstitial fibrosis we have spent the first year identifying populations and collecting sera from patients with silicosis and asbestosis plus appropriate controls. Early data are also available on the incidence of antinuclear antibody in these patients. During the 02 year, these findings will be extended to assaying sera for antibody to specific nucleic acids and other nuclear antigens, in an attempt to identify antigens which might act as diagnostic markers for patients with silicosis and asbestosis who develop associated connective tissue diseases. Concerning the project on mold sensitive environmental asthma, we have, during the 01 year, analyzed antigenic relationships among species of various aspergilli by RAST inhibition. During the second year, we shall attempt similar studies searching for shared antigens among various basidiomycete cultures and preparing basidiomycete antigens of cytoplasmic and metabolic origin.

SPOTTED FEVER IN TICKS, DOGS AND MAN ON CAPE COD
J.L. Waner, Harvard University, Boston Campus, School of Public Health, Dept. of Microbiology, *55 Shattuck St., Boston, Massachusetts* 02115 (R01 AI 13552-03S1)
Seven dogs from Cape Cod and 8 dogs from Martha's Vineyard were diagnosed clinically and serologically as having Rocky Mountain spotted fever; R. rickettsii was isolated from 3 of the dogs. R. montana, however, has been isolated from approximately 1% of the ticks examined. R. montana appears to have antigens in common with R. rickettsii as evidenced by antibody determinations made from the sera of sick and asymptomatic but sera-positive dogs. Sera from asymptomatic dogs previously shown to be reactive with R. rickettsii were reactive to the same or to a higher degree with R. montana.

FACTORS AFFECTING PREVALENCE OF HERPESVIRUS TYPE II
K.M. Stavraky, University of Western Ontario, Dept. of Epidemiology & Preventive Medicine, *1151 Richmond St., London, Ontario, Canada* N6A 3K7 (R01 AI 15974-01)
The purpose of this study is to determine the relationship between specific patterns of sexual behavior and the prevalence of antibodies to herpesvirus type II, and to determine whether these patterns vary by social class. The study will be useful in determining the sexual and socioeconomic risk factors for herpesvirus type II infection; this information will in turn assist in directing preventive measures to the highest risk groups. Prevention of infection is worthwhile because there is evidence that herpesvirus type II not only causes a number of usually minor ilinesses, particularly genital herpes, but also produces congenital malformations and neonatal disease in the offspring of infected women, and because this virus may be etiologically related to cervical cancer.
The study design is a cross-sectional survey of a sample of English-speaking men and women between the ages of 35 and 50, residing in Metropolitan Toronto. Information on specific sexual behavior, use of contraceptives and demographic attributes will be ascertained by interview and blood samples will be drawn for radio-immunoassay determination of antibodies to herpesvirus type II. A feasibility study of Toronto has demonstrated that a high proportion (90%) of eligible subjects respond favorably to the questionnaire and cooperate with a blood sample.

NEONATAL CHLAMYDIA INFECTION - INCIDENCE AND TREATMENT
E.R. Alexander, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105 (R01 AI 16110-01)
Chlamydia trachomotis, an intracellular parasite, is the etiologic agent of trachoma, non-gonococcal urethritis and inclusion conjunctivits. It can also infect the cervix of women and during pregnancy, the organism may be acquired by the infant during passage through the birth canal at delivery. The infant may subsequently develop inclusion conjunctivitis or pneumonia. We intend to investigate in this proposal, the risks and consequences of perinatal chlamydial infection and to explore various means of intervention and treatment.
These objectives will be accomplished by means of prospective incidence studies, prophylaxis and treatment trials: 1) We shall study the efficacy of prenatal treatment of pregnant women with chlamydial infection, with erythromycin on the eradication of the infection and the prevention of subsequent chlamydial infection in the infant. 2) Evaluate erythromycin ointment as an alternative neonatal ocular prophylaxis for the prevention of neonatal chlamydial infection. 3) Evaluate oral erythromycin versus topical sulfonamide for the treatment of neonatal chlamydial conjunctivitis. 4) Determine the incidence of pneumonia due to C trachomatis in infants under one year of age and evaluate the comparative efficacy of treatment with oral erythromycin or ampicillin. 5) Determine if C. trachomatis plays a role in middle ear disease in children, and finally 6) Investigate the prevalence of chlamydial infection in the families of infected infants.

PHYSIOLOGY AND METABOLISM OF LEGIONELLA PNEUMOPHILA
R.D. Miller, University of Louisville, School of Medicine, Dept. of Microbiology & Immunology, *101 W. Chestnut, Louisville, Kentucky* 40202 (R01 AI 16121-01A1)
Legionella pneumophila is the etiologic agent for a recently recognized and described form of acute pneumonia. Since its isolation less than three years ago, this bacterium has been the subject of extensive research in many areas of investigation. Only recently, however, has information begun to emerge which hints at the natural habitat of this bacterium,

how it is transmitted to humans, and how it is able to cause disease. An association with the water in air-conditioning systems, and the isolation of the bacterium from nonepidemic environmental water sources has suggested that the bacterium is ubiquitous in nature, but these studies did not define the physical and nutritional parameters of the habitat. This proposal is designed to provide a better understanding of the overall metabolic capabilities of this organism, and to determine the conditions (nutritional, physical, etc.) under which this bacterium is able to survive and/or grow in the environment. Using a chemically defined medium, we will investigate the specific nutrient requirements for growth. Corroborative data will be obtained by analyzing the incorporation of radiolabeled compounds into cellular components, oxidation of compounds as energy sources, and measurement of enzyme activities associated with these processes. We will also study various parameters of the survival of starvation in water or other aqueous environments. Variables to be studied include the influence of cell density and cellular morphology,presence of certain inorganic compounds, and the role of the storage polymer poly-Beta-hydroxybutyrate.

EPIDEMIOLOGY OF CHLAMYDIA TRACHOMATIS INFECTIONS

J.T. Grayston, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology, *4000 15th Ave. N.E., Seattle, Washington* 98105 (R01 AI 16222-01)

This project is designed to increase knowledge of the epidemiology of human Chlamydia trachomatis infections. The etiological role of these organisms in trachoma, non gonorrheal urethritis (of the male), inclusion conjunctivitis of the newborn, and pneumonitis of infancy has been established and much has been learned about the epidemiology of C. trachomatis infections of the eye, the genital tract, and newborns in both trachoma endemic and nonendemic areas of the world. Evidence regarding the disease significance of C. trachomatis infections of the female genital tract (cervicitis, salpingitis, peritonitis and perihepatitis) has been accumulating and studies of these infections are proposed. Although no etiological significance has yet been demonstrated, the organisms have been isolated from the middle ear, pharynx and the rectum. We have serologic epidemiological data from U.S. population groups strongly suggesting that these organisms cause more frequent infection than can be accounted for by known eye and genital tract disease. Our serological data suggests that C. trachomatis is etiologically associated with pneumonia of children after infancy and in adults. A series of studies of the role of C. trachomatis in pneumonia and acute lower respiratory disease are proposed. In addition we plan to utilize our unique specific serological test (micro immunofluorescence) for both serum and local secretions in preliminary studies of various disease syndromes potentially associated with C. trachomatis (acute respiratory disease, chronic obstructive pulmonary diseases, sinusitis, otitis, ideopathic inflammation of the bowel) to identify targets for some specific etiological and epidemiological studies. Patients with compromised pulmonary (e.g. cystic fibrosis) or immunological systems will be studied to determine the potential role of C. trachomatis in their disease process. Also, couples with infertility problems will be similarly investigated.

BASIC AND APPLIED RESEARCH IN PROTOZOAN DISEASES

T.C. Jones, Cornell University, Medical Center, Cornell Medical College, Dept. of Medicine, *1300 York Ave., New York, New York* 10021 (P01 AI 16282-01)

Diseases caused by the Leishmania-Trypanosoma complex are of major importance in the Wester Hemisphere. The diseases exhibit marked variation in clinical manifestations yet, taxonomically, biochemically and immunologically, they maintain many similarities which may provide clues to pathogenesis. Control of these diseases will result from careful evaluation of pathogenic mechanisms, antimicrobial therapy, disease patterns, and methods of accurate diagnosis. This program project brings together basic science and clinical investigators from Cornell University Medical College and The Rockefeller University and respected Brazilian investigators from the University of Bahia and the University of Brasilia. The central focus of this collaborative effort is the integration of basic and applied clinical research. The major research areas include: 1) basic parasitology, immunobiology and pharmacology of Chagas' disease and leishmaniasis; 2) clinical disease patterns, epidemiology and genetics these disease; and 3) application of immunologic techniques for understanding pathogenesis and for reliable diagnosis. Central to this grant is the attempt to coordinate the activities of investigators from different disciplines to allow exchange of limited resources, to bring these investigators in contact with young researchers abroad, and to advance our understanding of important human diseases.

SERODIAGNOSIS OF SUBCLINICAL LEPROSY (PROPOSAL I)

T.M. Buchanan, University of Washington, School of Medicine, Dept. of Medicine, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (R21 AI 16290-01)

We propose to develop an enzyme-linked immunoassay (ELISA) and a radioimmunoassay (RIA) capable of detecting antibodies to M. leprae specific protein antigen(s) to be used in an immuno-epidemiological study of leprosy in the countries of Sri Lanka (Proposal II) and Mexico (Proposal I). Antibody levels and skin test results will be obtained from untreated contacts of leprosy patients. This information will be correlated with subsequent development of tuberculoid leprosy (T) or lepromatous leprosy (L) in contacts with frequent or less frequent exposure to leprosy patients.

Experiments will be performed to learn more about purification of leprosy bacilli from host tissues without the use of proteolytic enzymes. We will concentrate on protein antigens on the surface of M. leprae since we have obtained evidence outlined below that an antigen(s) exists that is relatively specific for M. leprae and that it is a protein located on the surface of M. leprae. This protein will be purified to a single component as evaluated by SDS polyacrylamide gel electrophoresis and its molecular weight and isoelectric point will be determined. It will then be used in a quantitative immunoassay to detect specific antibodies to this protein in sera from leprosy patients or contacts with leprosy patients. Antigen fractionation and purification will be performed both in Mexico and Seattle, and use of the purified M. leprae specific protein in a quantitative Enzyme Linked Immuno Sorbant Assay (ELISA) will be performed in all three countries. Personnel from the University of Washington will spend 5-6 months per year in each country to assist the development of the ELISA method and its application for testing sera contacts of leprosy patients. Separate funding will be sought to allow 2-6 month training periods for one collaborator each year either from Mexico or Sri Lanka to learn new immunochemical techniques in the Seattle laboratory.

GENETICS OF IMMUNE RESPONSE IN MAN

D.G. Marsh, Johns Hopkins University, School of Medicine, Dept. of Medicine, *725 N. Wolfe St., Baltimore, Maryland* 21205 (P01 AI 13370-03S1)

Human immune response phenotypes, including specific IgE and IgG antibody and lymphocyte responses to ultrapure pollen allergens, and total basal serum IgE level, are of uncertain genetic determination. These phenotypes will be explored for consistency, familial aggregation and genetic determination in people selected for allergy and their families. If these traits are indeed found to be Mendelian, then linkage analysis and genetic mapping, including possible mapping of Ir loci in the major histocompatibility complex, will be done.

Populations to be studied include a series of allergic volunteers; a set of family-based Amish rural dwellers; and a new group of allergic persons identified from an occupational survey (with suitable comparison groups).

Particular features of this project will be: (1) the use of ultrapure allergens for all immunologic analysis; (2) serological typing of non-HL-A antigens expressed on lymphocytes; (3) careful study and characterization of the mixed lymphocyte response; (4) use of Galtonian as well as Mendelian genetic models in statistical analysis; (5) development of new techniques for linkage analysis of closely-linked loci in human populations.

We anticipate that many new findings concerning the genetics of allergy and immune response in man will emerge from this project which will be of direct relevance in our understanding of human disease.

DIABETES IN THE PACIFIC - GENETIC-ENVIRONMENT INTERACTIONS

P.Z. Zimmet, Royal Southern Memorial Hospital, Dept. of Metabolic Medicine & Epidemiology, *260 Kooyong Rd., Box 185 Caulfield S., Melbourne, Victoria, Australia* (R01 AM 25446-01)

The major objectives of the proposed research are to determine: a. whether specific genetic markers exist in the maturity-onset diabetic or in individuals who have predisposing genes for diabetes. b. whether the differing susceptibility of various ethnic groups to maturity-onset diabetes is related to the pesence or absence of these genetic markers. c. to establish the relative role of other factors such as age, nutrient intake, physical activity, obesity, stress, etc. in the causation of diabetes in genetically susceptible individuals. d. the definition of possible preventative factors relating to diabetes in high prevalence populations. On the basis of these findings it is hoped that intervention programmes might be undertaken.

It is hoped to achieve these objectives by measurement of genetic markers (e.g., tissue typing, red blood cell enzymes and serum proteins with known gene loci). The studies will be carrid out on Caucasian, Melanesian, Polynesian, Micronesian, and American Indian populations.

Such a study provides a broad spectrum of ethnic groups with varying susceptibility to diabetes. It will allow the comparison of genetic and various environmental factors which may influence the development of diabetes in these populations.

SEXUAL DISORDERS RESULTING FROM DIABETES

G.G. Abel, Columbia University, College of Physicians & Surgeons, Dept. of Psychiatry, *630 W. 168th St., New York, New York* 10032 (R01 AM 25630-02)

An estimated 30 to 50% of female and male diabetics develop significant sexual disorders as a result of their diabetes and yet little is known about the extent of the emotional consequences of these dysfunctions, how to separate dysfunctions resulting from organic versus psychogenic causes, how effective current sexual re-education programs are at reversing the emotional consequences of the organic dysfunctions. Furthermore, few members of the diabetic team understand how to recognize these sexual disorders or how to treat them. The research team is employing controlled group studies and the clinical interview, attitudinal measures and physiological sleep recordings of genital arousal, to (1) objectively assess the prevalence of sexual disorders and their emotional consequences in male and female diabetics, (2) validate physiologic methods to separate common organic disorders from psychogenic disorders, (3) objectively measure the prevalence of organic sexual disorders in diabetics reporting impotence or nonorgasmia and (4) evaluate the effectiveness of sexual counseling at teaching alternative sexual styles to the organically dysfunctional. Finally, (5) teaching materials will be developed and demonstrated to teach the diabetic team accurate diagnosis and treatment of these sexual disorders.

GENETIC EPIDEMIOLOGY OF DIABETES IN RUBELLA DEAFNESS

W.E. Nance, Virginia Commonwealth University, School of Basic Sciences & Graduate Studies, Dept. of Human Genetics, *901 W. Franklin St., Richmond, Virginia* 23284 (R01 AM 25786-01)

A five-year prospective study will be conducted to determine the prevalence and incidence of metabolic and immunologic indices of islet cell damage and/or glucose intolerance in a cohort of 100 adolescent children with rubella embryopathy at the Maryland School for the Deaf in relation to the maternal and offspring HLA phenotypes. The study will thus exploit the naturally occurring paradigm of isletopathy in children with congenital rubella who were born during the 1964-65 pandemic to test the general hypothesis that diabetes can arise from a genetically determined adverse host response to viral infection either in the affected individual or in the mother during pregnancy. The study will further define the rubella syndrome and could lead to the identification of specific maternal factors that are of importance in the etiology of diabetes and birth defects. Longitudinal observations of blood glucose and insulin response to a standard oral glucose challenge will be obtained along with C-peptide assays, insulin antibody determinations, Hb Alc measurements and screening for auto-antibodies to islet cells and other tissues. These studies, along with HLA typing, will permit an accurate characterization of the type of juvenile diabetes that occurs in the rubella syndrome as well as providing evidence as to whether immunoglogic abnormalities can precede or only follow the onset of glucose intolerance in this high-risk population.

AROMATIC AMINES AND LUPUS ERYTHEMATOSUS

M.M. Reidenberg, Cornell University, Medical Center, Cornell Medical College, Dept. of Pharmacology, *1300 York Ave., New York, New York* 10021 (R01 AM 25963-01)

Observations that implicate aromatic amines and not their acetylated metabolites as a cause of systemic lupus erythematosus (SLE) have been made. We plan to definitively evaluate this in man by comparing the rate of development of ANA in patients receiving procainamide with that in patients receiving N-acetylprocainamide. We also plan to study the rate of ANA development in mice fed procainamide, acetylprocainamide, aromatic amines from food dyes including FD and C Red number 2 and its reduction product, naphthionic acid, and N-acetylated naphthionic acid, and hair dye constituents including diaminoanisole and its N-acetylated product to learn if environmental aromatic amines can incite ANA production and learn the structure-activity relationship for this effect. We plan to study both transglutaminase activity in plasma and whole body N-oxidizing activity of patients with idiopathic SLE and compare them to appropriately selected controls to learn if patients with SLE have high activity of these two pathways by which an aromatic amine might be convalently bound to a nuclear macromole making it foreign and antigenic. If either of these pathways are active in SLE, family studies of the patients will be done to evaluate the role of inheritance in the activity of the pathway.

COMPARISON OF OVERWEIGHT AND OBESITY AS RISK FACTORS

J. Habicht, Cornell University, Ithaca Campus, New York State College of Human Ecology, Division of Nutritional Sciences, *Ithaca, New York* 14850 (R01 AM 26236-01)

We propose to do an epidemiological analysis of existing data derived from the Health Examination Survey on the adult populaton of the U.S. as the basis for an analysis of the relationships between obesity and overweight, with carbohydrate tolerance and blood pressure. We will use anthropometric measurements to characterize different physiologically meaningful variables, such as obesity, which are related to overweight. We will then ascertain which of these variables are most closely associated to blood pressure and glucose tolerance, and hypertension and diabetes, in the sense of pathologically elevated blood pressure and impaired glucose tolerance, according to accepted criteria. Our purpose is to identify risk indicators for diabetes and hypertension and to clarify the biological basis for the association of diabetes and hypertension with overweight. In addition, we wish to evaluate the relative utility of different indicators of weight and fatness in epidemiological studies.

WORKSHOP - GENETICS AND HETEROGENEITY OF GI DISEASES

D.L. Rimoin, University of California, Los Angeles Campus, Los Angeles County Harbor General Hospital, Division of Medical Genetics, *1000 W. Carson St., Torrance, California* 90509 (R13 AM 26714-01)

The methods of genetics are powerful tools for increasing our understanding of the etiology and pathogenesis of disease. This is especially so when such studies utilize all the physiologic and biochemical tools available to delineate the heterogeneity of what may first appear to be one disorder.

The purpose of this workshop is to bring together an interdisciplinary group of investigators - gastroenterologists, geneticists, epidemiologists, physiologists - to 1) discuss the current state of knowledge of the genetics and heterogeneities of common gastrointestinal disorders, 2) to delineate what areas would benefit from application of currently existing technology and methodologies, and 3) to foster interdisciplinary approaches and collaborative efforts in future studies. The ultimate goal of this workshop is to stimulate research into the genetics of the gastrointestinal disorders, thereby increasing our knowledge of the etiology, pathogenesis, and natural history of this group of disorders.

HEMOGLOBIN A, LEVELS IN DIABETES

P.H. Bennett, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Arthritis Metabolism & Digestive Diseases, Southwestern Field Studies Section, *Phoenix, Arizona* 85016 (Z01 AM 54021-01 DD)

Glycosylated hemoglobin concentrations were measured in 400 Pima Indians, aged 15 to 91 years, who were participating in the epidemiological studies of diabetes in the Gila River Indian Reservation in Arizona. At the same time plasma glucose levels, fasting and two-hours post-glucose load (75g), were determined and compared with the hemoglobin to see which test might be the best indicator of the presence of diabetes. Previously the glucose levels, have been described by a model of two overlapping Gaussian distributions. Attempts were made to fit the same model to the glycosylated hemogiobin concentrations. Only a single distribution was observed in the young males (15 to 24 years). In the young females a single model was seen corresponding to the normal population with a few outlying values indicating the presence of a small number of diabetics in this age group. In those aged 25 years and over, the glycosylated hemoglobins were bimodally distributed and like the glucose levels were a satisfactory fit to the overlapping Gaussian distribution model. These observations indicate the presence of two subpopulations in the Pima Indians, one normal and one diabetic.

DESCRIPTIVE EPIDEMIOLOGY OF GLOMERULONEPHRITIS AND OTHER URINARY DISORDERS

J.A. Cutler, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Arthritis Metabolism & Digestive Diseases, Epidemiology & Field Studies Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 AM 69012-01 EFS)

This project applies an orientation to specific renal and urinary diseases to analysis of previously collected data from death certification and health surveys. Distribution of morbidity and mortality by secular time, geography, and personal characteristics in the U.S. population is being compared to previous studies in selected groups. The main purposes of this work are (1) to examine the plausibiliy of various etiologic hypotheses, especially for glomerulonephritis, and (2) as an aid to planning epidemiologic studies, including future versions of NCHS health surveys and specific analytic studies.

STUDY OF HYPERPARATHYROIDISM - ETIOLOGY, DIAGNOSIS AND TREATMENT

G.D. Aurbach, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Arthritis Metabolism & Digestive Diseases, Metabolic Diseases Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (R01 AM 43006-04 MD)

The project goal is the evaluation and treatment of hyperparathyroidism. Patients with persistent postoperative hyperparathyroidism are referred for evaluation and treatment. Hereditary hyperparathyroidism in particular is under investigation in the hopes of delineating hereditary molecular abnormalities in glandular regulation, as exemplified in the multiple endocrine neoplasia syndromes. Evaluation ranges from epidemiologic studies of families to in-house studies of patients and to in vitro analyses of excised tissue. Techniques currently being employed and improved include radioimmunoassay of parathyroid hormone, selective arteriography and selective venous sampling for parathyroid hormone, parathyroid gland cryopreservation and autotransplantation, and transcatheter parathyroid gland infaraction.

COMPLICATIONS AND OUTCOME OF DIABETIC AND PREDIABETIC PREGNANCIES

P.H. Bennett, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Arthritis Metabolism & Digestive Diseases, Southwestern Field Studies Section, *Phoenix, Arizona* 85016 (Z01 AM 69001-10 EFS)

To determine the effects of diabetes mellitus and prediabetes on the complications and outcome of pregnancy in women in the Gila River Indian Community.

The characteristics of all pregnancies among residents of the Gila River Indian Community will be determined. Each pregnant woman will have a modified glucose tolerance test during the third trimester and following delivery and will be retested at approximately two yearly intervals in conjunction with the prospective study of diabetes mellitus in the same community. The characteristics of the pregnancies in women who subsequently become diabetic will be compared to those among women who were diabetic at the time of pregnancy and those who remain nondiabetic.

GILA RIVER INDIAN COMMUNITY AUTOPSY STUDY

P.H. Bennett, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Arthritis Metabolism & Digestive Diseases, Southwestern Field Studies Section, *Phoenix, Arizona* 85016 (Z01 AM 69006-08 EFS)

The postmortem characteristics of Pima Indians of the Gila River Indian Community will be investigated so that findings in subjects with and without diabetes mellitus can be correlated with studies in living subjects.

Postmortem examinations will be performed on members of the Gila River Indian Community whenever possible, regardless of whether the subjects have prior evidence of diabetes. Tissues will be examined by light and electron miscoscopy and the histology related to the clinical findings in the same subjects. Trace metal contents of tissues will be measured to determine relationships of trace metals to diabetes. The data collection will be continued for several years with periodic analyses of the data.

NATURAL HISTORY OF ARTHRITIS AND RHEUMATISM ON THE GILA RIVER INDIAN COMMUNITY

P.H. Bennett, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Arthritis Metabolism & Digestive Diseases, Southwestern Field Studies Branch, *Phoenix, Arizona* 85016 (Z01 AM 69009-14 EFS)

The development and progression of various forms of arthritis is being investigated in an American Indian population. The patterns of joint disease will be examined to determine if distinctive patterns of degenerative joint disease can be recognized, and if so, their evolution and outcome will be followed. In addition, the prognostic significance of various factors related to rheumatoid arthritis and ankylosing spondylitis will be examined.

The study which includes clinical, radiographic and serologic studies of joint disease is part of a prospective study of the Gila River Indian Community, in which studies of diabetes mellitus and related diseases are being undertaken.

LYME ARTHRITIS - A NEW EPIDEMIC DISEASE

A.C. Steere, Yale University, School of Medicine, Dept. of Medicine/Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (R01 AM 20358-03)

We have recently uncovered a new, epidemic disease, Lyme disease, probably caused by an infectious agent transmitted by Ixodes dammini ticks. In Lyme disease, immune complex formation is associated with lesions in the skin, joints, heart, or nervous system. We plan to define the natural history of this illness, its course and prognosis, etiology, vector, and pathogenesis. To accomplish these objectives, a surveillance network of primary physicians has been established to refer patients with Lyme disease; the natural history of the illness will be described from the serial examination of these patients. All patients will be contacted at least yearly to gain information about recurrent symptoms. All cases reported to us from physicians outside Connecticut will be computed to determine the geographic distribution of the disease in the United States. Immune complexes and cryoprecipitates will be sought for in the sera of each patient at each visit, and characterized. In collaboration with Dr. Robert Winchester at Rockefeller University, complete immunogenetic profiles will be done on selected patients and their families. The natural cycle and preferred hosts of Ixodes dammini will be studied in the field. Ixodes dammini collected in the field will be pooled and extracts inoculated into tissue cultures, mice, and monkeys. Tissue culture cells and skin biopsy specimens will be examined by indirect immunofluorescence. Immune complexes will be fractionated and an attempt made to identify putative antigens. If a serologic test can be developed for Lyme disease, positive diagnosis will be possible in all affected patients, and studies will be conducted to determine attack rates within sample human and animal populations. The results would provide the basis for decisions about control measures.

FAMILIAL AGGREGATION OF INFLAMMATORY BOWEL DISEASE

A.M. Lilienfeld, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Epidemiology, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 AM 20467-02)

This study is attempting to determine if family members (parents, siblings, offspring, and spouses) of newly hospitalized cases of ulcerative colitis and proctitis, regional enteritis, and Crohn's disease of the colon have greater prevalence of these diseases than family members of controls. Newly hospitalized cases are being ascertained through a case register in Baltimore and from local hospitals. Medical records of cases are being abstracted; and reviewed by a gastroenterologist. Cases and family members will be interviewed regarding previous illnesses; tobacco, alcohol, and dietary habits; and demographic characteristics. Information will be obtained concerning all family members, living and dead.

Hospital controls will be matched by sex, color, and age to each case. Hospital controls and their family members will be interviewed in the same manner as cases, and medical records will be obtained. Neighborhood controls will be matched to cases by sex, color, and age. These controls and their family members will be interviewed in the same manner as cases, and medical records will be obtained. Death certificates will be obtained for all cases and family members who have died.

Serum will be collected from cases, controls, and family members, and will be frozen at -70 degrees centigrade for future studies.

SPECIALIZED CENTER OF RESEARCH IN UROLITHIASIS

L.H. Smith, Mayo Foundation, *200 1st St. S.W., Rochester, Minnesota* 55901 (P50 AM 20605-03)

The central research theme of the Mayo Clinic Specialized Center of Research (SCOR) in Urolithiasis is to examine the factors that promote and prevent crystal growth within the urinary tract in order to

further understand the mechanisms that allow stone formation and to improve treatment to prevent this complication. The specific objectives of the Mayo Clinic SCOR in Urolithiasis are: 1) to examine sites of reabsorption and secretion of the major ion species within the nephron; 2) to better define the relative roles of supersaturation, inhibitor activity, matrix and epitaxy in animal models and patients with calcium urolithiasis; 3) to measure the effect of therapy on the multiple factors involved in crystal growth in the urine of patients actively forming stones in the urinary tract; 4) to identify abnormalities caused by stone producing stresses that result in urolithiasis in some patients as well as prestress abnormalities that may allow the formation of a stone within the urinary tract; and 5) to study in a systematic way the epidemiology and genetics of urolithiasis in a well defined population base.

EPIDEMIOLOGY OF DIABETES AMONG NEW IMMIGRANT YEMENITES

A.M. Cohen, Hebrew University of Jerusalem, Hadassah University Hospital, Diabetic Unit, *P.O. Box 499, Jerusalem, Israel* (R01 AM 20733-03)

We propose to extend our recent preliminary observations in 'new immigrant Yemenites' who had a low prevalence of diabetes (0.03%) in the years 1958-60 showing that in part of the families diabetes has become highly prevalent (9%) above the age of 30, while in other families no diabetes was detected. In families with diabetes, the diabetics consume significantly more mono and disaccharides than non-affected relatives of the same age and sex. Indicating the necessity for interaction between genetic and dietary factors for diabetes to be manifested, a result similar to our experimental observation where, by genetic selection, two strains of rats were inbred, one which after being fed a high fructose (1), glucose (2) or sucrose (3) diet develops diabetes, having common features with the human disease including vascular complications while the other strain fed the same diet remains normal. 700 more 'new immigrant Yemenites' and 300 non-Yemenites as controls will be re-examined. Diabetes will be detected by an oral glucose tolerance (g.t.) the genetic familial tree and dietary intake - carbohydrate, mono and disaccharides, fat, protein and fiber - of each individual will be studied.

We will also try to identify marker(s) of diabetes in the affected and non-affected families by the following tests: a) early phase of insulin release following i.v. g.t.; b) glucagon response; c) insulin receptors in blood granulocytes; d) blood lipids - beta lipoproteins, cholesterol, triglycerides and LDL; e) HLA antibodies and f) antipancreatic islet cells.

The proposed study in a group with almost no diabetes 20 years ago that has changed to a Western environment and in which there are today families with a high prevalence of diabetes and families without diabetes is a unique group to study the interaction of the genetic factor(s) and the different factors related to the manifestation of diabetes such as sex, obesity, age, physical activity, dietary intake, and the different tests which may be used as indicators for the genetic susceptibility to diabetes.

SEXUAL DISORDERS RESULTING FROM DIABETES

G.G. Abel, University of Tennessee, Center for the Health Sciences, School of Medicine, Dept. of Psychiatry, *62 S. Dunlap St., Memphis, Tennessee* 38103 (R01 AM 20844-01S1)

An estimated 30 to 50% of female and male diabetics develop significant sexual disorders as a result of their diabetes and yet little is known about the extent of the emotional consequences of these dysfunctions, how to separate dysfunctions resulting from organic versus psychogenic causes, how effective current sexual re-education programs are at reversing the emotional consequences of the organic dysfunctions. Furthermore, few members of the diabetic team understand how to recognize these sexual disorders or how to treat them. We propose using, controlled group studies and the clinical interview, attitudinal measures and physiological sleep recordings of genital arousal, to 1. objectively assess the prevalence of sexual disorders and their emotional consequences in male and female diabetics, 2. validate physiologic methods to separate common organic disorders from psychogenic disorders, 3. objectively measure the prevalence of organic sexual disorders in diabetics reporting impotence of nonorgasmia, and 4. evaluate the effectiveness of sexual counseling at teaching alternative sexual styles to the organically dysfunctional. Finally, 5. teaching materials will be developed and demonstrated to teach the diabetic team accurate diagnosis and treatment of these sexual disorders.

2.0961,

DIABETES MELLITUS AND SEXUAL DYSFUNCTION

R.C. Schiavi, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Psychiatry, *5th Ave. at E. 100th St., New York, New York* 10029 (R01 AM 20845-03)

Although the association of diabetes and potency disorders is well recognized, there is limited information on the pathophysiology of erectile disorders in the diabetic male and few procedures that may assist in the differential diagnosis between psychogenic and organic importance. There is also an almost total lack of information concerning the influence of diabetes mellitus upon sexual function in the female patient.

The overall objective of this application is to study sexual dysfuntions in diabetic patients. Studies are proposed to gather data on the prevalence and nature of sexual problems in a population of female diabetics. For this purpose, a detailed semi-structured interview, and a self-report scale of sexual function will be completed by a group of female diabetics and a comparison group of non-diabetic patients. The second objective of the proposed research is to evaluate the diagnostic value of assessing nocturnal penile tumescence for the evaluation of potency disorders in diabetic male patients. For this purpose, the nocturnal erection pattern of four groups of subjects are compared: diabetic men from sexual disorders, diabetic men with erectile dysfunctions, psychologically impotent non-diabetic men and normal controls.

EPIDEMIOLOGICAL STUDY OF ANALGESIC USE AND RENAL DISEASE

T. Murray, University of Pennsylvania, School of Medicine, Dept. of Medicine, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (R01 AM 20920-02S1)

The purpose of this study is to determine the 'relative risk' of developing end-stage renal disease secondary to chronic interstitial nephritis after the use of various types and total doses of analgesics. The methodology being employed is that of a case control study. The cases are patients with end-stage interstitial nephritis who are on dialysis in the Greater Delaware Valley (South Eastern Pennsylvania and South Western New Jersey). The controls will consist of three groups: 1) patients on dialysis from the same area who have chronic glomerulonephritis, 2) hospital controls; and 3) community controls. Utilizing data obtained from questionnaires and from the abstracting of medical records, it will be possible to characterize a dialysis patient as having chronic interstitial nephritis or chornic glomerulonephritis and to determine if various causes (other than analgesic use) for either were present. In addition, a detailed quantitative estimate of analgesic consumption over the last 20 years will be obtained. Comparison of the analgesic exposure of cases and each of the control groups will permit calculation of a relative risk statement.

DIABETES--PATHOGENESIS, DETECTION, AND ORAL AGENTS

J.S. Soeldner, Joslin Diabetes Foundation Inc., Elliott P Joslin Research Laboratory, *170 Pilgrim Rd., Boston, Massachusetts* 02215 (R01 AM 09748-13)

To clarify the genetic components of human diabetes, a prospective study of the offspring of two diabetic parents and the apparently unaffected monozygotic twins with a diabetic twin mate will be continued and extended. Emphasis will be placed upon the determination of histocompatibility antigens and the relationships of these antigens to the presence or absence of overt diabetes and/or carbohydrate intolerance as evaluated by oral glucose tolerance test and other appropriate perturbations. Detailed evaluations of serum insulin, plasma glucagon and serum growth hormone responses will be made and related to histocompatibility antigens. Extensive evaluations of plasma cholesterol, HDL cholesterol and triglycerides will also be determined and related to the metabolic-hormonal aspects.

In all of these prospective studies, glycosylated hemoglobin would be evaluated at least three times per year in all study groups and in appropriate normal controls.

To determine the relationship between the degree of diabetes (from frank overt diabetes to mild chemical diabetes) on capillary morphology, muscle capillary basement membrane thickness will be evaluated by electron microscopy in study subjects.

The mechanism of insulin secretion in these groups (generally characterized by a small but significant defect in insulin release) will be pursued by evaluating insulin secretion following the administration of not only glucose but also various hexoses other than glucose and evaluating the subsequent insulin responses, glucose utilization ad also by gastric inhibitory polypeptide determinations.

HORMONES AFFECTING MINERAL METABOLISM

A.H. Tashjian, Harvard University, Boston Campus, School of Public Health, Dept. of Physiology, *55 Shattuck St., Boston, Massachusetts* 02115 (R01 AM 10206-14)

The broad objectives of this research plan are to investigate three kinds of hormonal or locally produced agents that affect mineral metabolism in bone. Studies will focus on: 1) Calcitonin, 2) nonpeptide factors (especially prostaglandins), and 3) parathyroid hormone. Calcitonin receptors in bone will be characterized, and the control of their modulation and role in 'escape' from the biological actions of the peptide will be studied. Calcitonin biosynthesis in normal and malignant thyroid C-cells and in other tissues will be investigated. Additional studies in human medullary thyroid carcinoma will focus on cellular immune mechanisms, pharmacological control, and epidemiology. New studies on two prostaglandin-producing tumors in animals will serve as models for the hypercalcemias of cancer; these include examination of the mechanisms of action of prostaglandins in bone, the role of local prostaglandin production by bone cells, and the metabolism of prostaglandins by bone. Studies of parathyroid hormone will probe its mechanisms of action on bone cells, including localization and characterization of its receptors, and the role of vitamin D in parathyroid hormone biosynthesis and release. The experiments proposed are designed to investigate several fundamental aspects of hormones affecting mineral metabolism in in vitro and animal models and to relate these findings to clinically important disorders of bone metabolism in man.

THE ROLE OF VIRUSES IN RENAL TRANSPLANT PATIENTS

H.H. Balfour, University of Minnesota, Minneapolis Campus, School of Medicine, Dept. of Laboratory Medicine & Pathology, *1305 Mayo, Minneapolis, Minnesota* 55455 (R01 AM 18883-04)

The majority (70-90%) of renal transplant patients have evidence of viral infection, usually with cytomegalovirus (CMV), during the first months post-transplant. Preliminary, mostly retrospective studies at our institution and elsewhere have indicated an association between viral infections and acute febrile illnesses, transplant rejection and mortality. However, answers are needed to the questions 1) what is the source of the patient's virus? 2) do viruses cause clinically important illness? 3) how do viral infections affect immune function and relate to episodes of transplant rejection? 4) do viruses other than CMV play a significant role? Our objective is to answer these questions by performing an intensive prospective epidemiologic viral study. The source of virus will be sought by culturing donors, donor organs, transplant staff, and blood products which the patients receive. CMV isolates and patient sera will be studied for strain specificity which might indicate whether CMV infections are exogenous or reactivation of latent infection. The relationship of viral shedding with serious clinical illness will be examined by prospective studies of the patients with frequent viral culturing and detailed clinical observations. Nonspecific and specific humoral and cell-mediated tests will be done to examine the relationship of viral infection to immune function, and these studies will be correlated with episodes of rejection. The tests include quantitation of T and B cells, a battery of viral antibody titers with emphasis on herpesviruses, mitogen stimulation using PHA, Con A, and CMV antigen, mixed lymphocyte culture, lymphocyte mediated cytotoxicity toward CMV antigen, and allogeneic induced CMV release from patient lymphocytes. The virologic technics will enable us to study the role of viruses other than CMV. These studies have broad implications for elucidating the etiology and managing episodes of transplant rejection, and for providing appropriate epidemiologic, prophylactic and therapeutic approaches for the prevention or treatment of virus infections in renal transplant patients.

JUVENILE DIABETES MELLITUS - EPIDEMIOLOGY & ETIOLOGY

A.L. Drash, Childrens Hospital of Pittsburgh, Division of Endocrinology Metabolism & Diabetes Mellitus, *125 De Soto St., Pittsburgh, Pennsylvania* 15213 (R01 AM 24021-02)

The incidence of J.O.D. less than 16 years of age will be determined for the first time in a defined community. The incidence will be related to age, sex, race and geographic area of residence. Seasonal and temporal trends will be evaluated. Secondary cases of J.O.D. within families during a 10 year follow up will be identified. The interrelationship of the demographic characteristics with HLA type, immunoglobulin and autoantibodies within and between families will be measured. Genetic analysis will include analysis of both immediate and extended families and will include HLA typing, immunoglobulin and autoantibody studies. The distribution of glucose tolerance within the families in relation to immunology, genetic and epidemiological characteristics will be considered. Viral antibody studies at the time of the initial diagnosis of a case within a family and prior to secondary case will be also be included. These studies should help determine the interrelationship of host and environmental factors in the etiology of J.O.D.

DYSPEPSIA, PEPTIC ULCER AND ITS COMPLICATIONS

J.H. Kurata, University of California, Los Angeles Campus, School of Public Health, Dept. of Epidemiology, *405 Hilgard Ave., Los Angeles, California* 90024 (R01 AM 25330-01)

This proposal is divided into three sections, each designed to further elucidate the epidemiology of peptic ulcer disease: Section one - Dyspepsia negative to all tests and duodenal ulcer. Three samples will be drawn from patients from the Wadsworth V.A. clinics: 100 men with duodenal ulcer; 100 men with dyspepsia negative to all tests; and 100 control men without any history of ulcer disease matched to the duodenal ulcer cases on the basis of age and race. Risk profiles, based on medical, psycho-social and biochemical variables, will be developed for each of these groups. The dyspeptics negative to all tests will be compared with the duodenal ulcer cases and the controls to determine if this group, or a subset, can be considered as representing a pre-ulcer population. Section two - Complications of peptic ulcer. One hundred men with a history within the past year of complications of peptic ulcer will be matched by age, race and duration of ulcer symptomatology to male ulcer patients with no history of complications. Risk profiles, similar to those described above, will be developed for each group. Efforts will be made to determine whether such a profile can help identify ulcer patients at high risk for future complications. Section three - Through a subcontract, investigate the interaction of genetic and environmental factors in peptic ulcer. First degree relatives of the subjects in the above sections will be studied in an attempt to evaluate the interaction of specific environmental factors with specific genetic forms of the spectrum of peptic ulcer disease.

LIFE STYLES AND BONE DENSITIES OF THE AGED

R.B. Sandler, University of Pittsburgh, School of Health Related Professions, Division of Interdisciplinary Programs, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (R01 AM 21190-02)

Two objectives were targets of the first year of a 2-year project, designed to provide a methodological baseline for a later study on the relationship in postmenopausal women between Life Styles and Bone Densities.

The first objective was to refine the method of bone density measurement with Computerized Axial Tomography (CAT) by: (1) identifying the major sources of variability in the precision of CT scanning and accuracy of bone density measurement, (2) devising means of achieving accurate long-term, high-precision bone density measurements at the lowest possible radiation.

To this end glass rod phantoms were employed to calibrate the machine and heavy tungsten filters were used to remove most of the lower energy x-rays. The use of filters produced a more nearly monochromatic beam and reduced the x-ray dose of each scan to about 80 mrem. With the reduction in x-ray dose, three separate scans could be used for each measurement of bone density to average out the variability due to longitudinal positioning of the limb and thus increase the precision of the method.

The second objective was to recruit postmenopausal volunteers and characterize them with respect to specific epidemiological parameters --that, on analysis, may be correlated with the density values in long bones. The volunteers were successfully recruited and are now being processed for the relevant data.

CAUSES OF DIABETES AND OBESITY IN OKLAHOMA INDIANS

K.M. West, University of Oklahoma, Health Science Center, College of Health, Dept. of Biostatistics & Epidemiology, *Box 26901, Oklahoma City, Oklahoma* 73190 (R01 AM 21462-02)

In the etiology of diabetes the strength and character of the genetic influences have been poorly defined. Among the main reasons for this are the inadequacies of the data collected, particularly those concerning the present and previous fatness of both probands and family members. In a whole population of Indian adults in which diabetes and obesity are rife, a study is proposed in which data collection would be uniquely complete, including information on glucose tolerance and both present and previous adiposity on all available adults (about 3,200). This will include about 700 with fasting hyperglycemia and several hundred more with varying degrees of impairment of glucose tolerance. Propitious circumstances include the large families, the geographic proximity of family members, and a centralized record system that provides information (on weight and other data) extending over the past 40 years. This will allow a determination of the inter-relationships of obesity and heredity, including an assessment of the extent to which the familial aggregation of maturity-onset diabetes is secondary to the familial aggregation of obesity. Another aspect of the study will be comparison of familial patterns of insulin-independent diabetes of obese and insulin-dependent diabetes of the lean. In diabetes the extent to which there is familial concordance of susceptibility to retinopathy will be examined. Other observations will be designed to confirm that juvenile-onset diabetes is rare in Oklahoma Indians, and to explore possible causes of the paucity.

BONE QUALITY CHANGES IN HUMANS - A 20-YEAR FOLLOW-UP

A.N. Milner, Texas Womans University, College of Nutrition Textiles & Human Development, Dept. of Nutrition & Food Sciences, *Box 23925, Denton, Texas* 76204 (R01 AM 21518-02)

Approximately 1,000 persons who underwent bionutritional and medical tests (including radiographs of the hand and os calcis for x-ray bone mineral quantitation) will be retested after a 20-25 year time lapse. Changes in individual bone mineral content and corti-

cal volume during the intervening quarter century will be determined by radiographic densitometry using the Texas Woman's University method (with recently incorporated improved technology); direct radiographic scaling of bone morphology; and, terminally, by gamma ray absorptiometry using the Norland-Cameron method.

Bone changes during the time period will be compared with the 'normal' profile of bone development/regression currently being ascertained through our contractual work with the National Center for Health Statistics. This work encompasses bone mineral and cortical thickness measurements of 12,000 individuals who have been computer-selected by the Bureaus of Census to represent the United States population.

The specific aim of the proposed program is to determine if bone rarefaction with age is uniform and universal, or if nutritional, environmental/occupational, or pathologic factors are conducive to deviations from the normal profile which may result in the syndrome known as osteoporosis.

HEPATITIS B INFECTION AND REACTIONS TO HOMOGRAFTS

W.T. London, Inst. for Cancer Research, *7701 Burholme Ave., Philadelphia, Pennsylvania* 19111 (R01 AM 21958-01)

The objectives of this proposal are: 1) To test the hypothesis that survival of the kidney and bone marrow grafts in human is related to the response of recipients to hepatitis B infection before transplantation 2) To gain insight into the mechanism by which responses to hepatitis B virus (HBV) might be related to responses to organ grafts. Specifically, to test the hypothesis that there is cross reactivity between an antigenic determinant on HBV and a male associated antigen.

Preliminary observations of human kidney and bone marrow grafts suggest that recipients with antibody (anti-HBs) to the surface antigen of HBV (HBsAg) are likely to reject such grafts within six months of transplatation, particularly if the organ donor is a male. These and other epidemiological and experimental studies are consistent with the hypothesis stated above.

We plan to test this hypothesis by: 1) Extending the clinical and epidemiological studies of kidney and bone marrow transplantation in relation to the responses of graft recipients to hepatitis B infection before transplantation; 2) By investigating whether the postulated cross reacting antigen is present on sperm as shown by an association between antibodies to HBV and antisperm antibodies in humans (vasectomized men) or experimental animals; and 3) By studying in in-bred mice the mechanism of early rejection of male to female skin grafts from male donors by female recipients immunized against HBsAg.

EPIDEMIOLOGICAL STUDY ON ORAL CONTRACEPTIVE AND STROKE

L.P. Chow, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Population Dynamics, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 HD 11536-02)

The proposal is to study the association, if any, that exists between oral contraceptive usage and increased risk of stroke among married women of childbearing age in a developing country. The study will be undertaken with the epidemiological case-control approach. Taiwan is selected as the study site because of her excellent household registration and vital statistics system and medical care services.

The association between the use of hormonal contraceptives and thromboembolic diseases of the heart, lung and brain has now been fairly well established on a number of epidemiological studies conducted mainly in the United Kingdom and United States. Similar studies to confirm, or deny, such association is much needed in the developing countries where the genetic background, life style, and dietary habits of people are different. The family planning policy implication of the proposed study is self-evident.

In the coming (second) year, approximately 200 stroke patients, 400 hospital controls, and 400 matched healthy neighborhood controls will be additionally interviewed to bring up the total sample size for the entire study to 300, 600, and 600 respectively in these categories.

CONTRIBUTION OF IRON DEFICIENCY TO MENTAL RETARDATION

J.C. Martin, University of Washington, School of Medicine, Dept. of Psychiatry & Behavioral Sci, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (P01 HD 11680-01S1)

The most widespread nutritional deficiency in the country today is iron, particularly in pregnant women and children in different socio-economic strata. A variety of metabolic disturbances and physiological and developmental changes appear to be concommitants of iron deficiency during pregnancy, including low birth weights, increased still-birth rate, elevation of toxemia, and possible increases in fetal anomalies. Some studies suggest that iron deficient children have lower I.Q.'s and poorer academic performance. In addition they are described as inattentive, hyperactive, perseverative, and poorly integrated, all behaviors which would retard their learning and performance.

Recent evidence for central nervous system disorders from iron deficiency which involve the serotonin pathway and by implication mental function, led to the enclosed program project. This is a collaboration between the departments of Psychiatry & Behavioral Sciences, Pediatrics, Laboratory Medicine, Medicine, Biostatistics and the Child Development Mental Retardation Center.

Th metabolic and behavior concommitants of iron deficiency will be examined both longitudinally in the infants of iron deficient women, and cross-sectionally in iron deficient children. In addition an animal model will be utilized in parallel studies.

Eight senior investigators are submitting four related research projects to be performed collaboratively.

2.0989,

ESTIMATION OF DEMOGRAPHIC INDICES FROM IMPERFECT DATA

A.J. Coale, Princeton University, Woodrow Wilson School of Public & International Affairs, Dept. of Economics, *Box 430, Princeton, New Jersey* 08540 (R01 HD 11720-02)

The proposal is to carry out a program of research aimed at developing models of fertility, nuptiality, and mortality to serve as tools of estimation of demographic quantities from deficient and fragmentary data; to facilitate population projections; and, in general, to provide more reliable description of demographic patterns and trends than is possible on the basis of raw data adjusted by use of presently existing models. The development of refinement of model life tables will progress on three main fronts. First, it will make use of international data on causes of death which were not available when the Coale and Demeny model life tables were prepared. By disaggregating and recombining, using a pattern of weights, the life tables can take on greater biological realism. Second, there will be a refinement of the very early and very late ages, in which health changes have the most immediate impact. Third, greater use will be made of Brass' linear logit transformation of standard sets of survival probabilities. Model nuptiality patterns appear to fit the data so well that there is no intention to develop them further except indirectly in the fertility tables. Model fertility patterns are the most recent of the three types and, as is intended, can be considerably extended. Rather than working on purely empirical grounds, as the earlier proposal indicated, there will be an effort to integrate research on birth intervals in natural fertility populations and micro-level models of fecundability, and then to bring in the role of contraception.

DETERMINANTS OF CHILD MORTALITY

M.R. Rosenzweig, Yale University, Graduate School, Dept. of Economics, *206 Elm, New Haven, Connecticut* 06520 (R01 HD 12172-02)

The proposed research is concerned with the development of approaches to evaluating the impact of family planning and medical inputs on infant health. The major objective of the research is the measurement of the joint effects of family behavior, environmental factors and health program inputs, such as the use and availability of medical inputs, female labor-force participation, family size, cigarette smoking and pollutants, on infant mortality rates and birthweight. Statistical procedures will be used which take into account the potentially simultaneous nature of related household decisions and child health outcomes. Data on socioeconomic characteristics of family members, behavior, and measures of child health from national surveys will be analyzed in conjunction with aggregate data on the price and availability of various medical services in the region in which the household resides. The areal information on prices and conditions confronting the household may be assumed exogenous to its behavior and health outcomes. Linking this areal data to household records permits, therefore, one to identify how a variety of program activities and prices affect birthweight and child survival both directly and indirectly by influencing related household behavior. Within the limitations of existing data files and the many and imperfectly integrated hypotheses concerning the causes of child health status, the proposed research aims to test certain of these hypotheses in a common statistical and economic framework.

ELECTRON MICROSCOPY IN CONGENITAL VIRAL INFECTIONS

A.J. Nahmias, Emory University, School of Medicine, Dept. of Pediatrics, *1364 Clifton Rd. N.E., Atlanta, Georgia* 30322 (R01 HD 12358-02)

The proposed studies are aimed at extending our investigations on the possible role of microbial agents in the causation of major congenital malformations and/or significant acute clinical manifestations in the newborn. Electron microscopy (EM) and immune electron microscopy (IEM) will be applied to: (a) detect viruses (old or new) in the affected infant's urine, serum, cerebrospinal and/or ventricular fluid, throat or stool, which cannot be identified by more conventional virological techniques; (b) obtain a more rapid diagnosis of agents already known to be involved with these conditions, e.g. cytomegalovirus. Maternal serum will be particularly valuable to test by IEM, since the mother would be expected to have been infected with the putative agent involving her fetus. Any virus detected by these techniques will be: (a) studied as regards its possible causality to the disease process; (b) identified by its size, morphological and biochemical characteristics and by its effect in various tissue culture and animal systems. Infants will be followed by laboratory, clinical and epidemiological means to establish the consequences of such an infection.

The long-term goals of these investigations is to improve diagnosis, so as to permit earlier preventive and therapeutic measures, as well as to find newer agents that might be involved in major congenital malformations which affect at least 1% of all deliveries and for which a known cause (genetic, chromosomal or environmental) can be found in less than 5% of cases.

NEWBORN INTENSIVE CARE AND NEONATAL MORTALITY IN NYC

N.S. Paneth, Columbia University, College of Physicians & Surgeons, Dept. of Pediatrics, *630 W. 168th St., New York, New York* 10032 (R01 HD 12626-02)

The object of this study is to measure the impact of newborn intensive care on a geographically defined population, the newborns of New York City. The primary outcome of interest is mortality, from late fetal to infant, with particular emphasis on neonatal mortality and its subdivisions.

Using New York City live birth, infant death and fetal death certificates, we will examine mortality within birthweight categories in several different ways for each of three levels of neonatal care. This analysis will proceed both cross-sectionally and over time. We will also attempt to correlate characteristics of hospital functioning with outcome, and analyze the contribution of infant transport to the overall effect of new born intensive care.

We hope as a result to generate information that will provide a sound basis for perinatal planning and that will be a first step toward understanding the interaction between neonatal interventions and brain-damaging conditions of childhood.

2.0994,

PHARMACOKINETICS & TERATOGENICITY OF ANTICONVULSANTS

R.E. Ramsay, University of Miami, School of Medicine, Dept. of Neurology, *1400 N.W. 10th Ave., Box 520875, Coral Gables, Florida* 33152 (R01 HD 12740-01)

The objective of the proposed project is to study prospectively (1) the effects which pregnancy has on the epileptic patient and (2) the teratogenic effect of anticonvulsant drugs. Evidence to date indicates that pregnancy may alter the pharmacokinetics and metabolism of drugs. Alterations in drug dosages are definitely necessary to maintain seizure control during pregnancy. Seizures exacerbate in more than 50% of pregnant epileptics, even when drug dosages are appropriately changed. The frequency of this change has not been accurately documented and the etiology, which may be secondary to changing hormone levels, has not been clarified. Studies on teratogenesis of anticonvulsant drugs have concentrated on the changes in the children but have not examined the mothers during pregnancy to document their metabolic or drug status. In this project, we propose to examine both the mothers during pregnancy and their offspring. The children will be reexamined periodically for years. Major malformations occur in 6 to 8% of children born to mothers taking anticonvulsant drugs. Up to 30% may have dysmorphic features. Delayed maturation and development has also been reported to occur but the true incidence, severity and etiology has not been defined. In this study, we hope to elucidate some of these questions by monitoring the mothers during pregnancy and serially examining the children for neurological, developmental and morphologic abnormalities.

FUNCTIONAL BIOCHEMICAL IMPACT OF MICRONUTRIENT DEFICITS

E. Pollitt, University of Texas, Health Science Center at Houston, School of Public Health, Dept. of Nutrition & Behavioral Sciences, *6515 Freeman, Houston, Texas* 77025 (R01 HD 12843-01)

In connection with an aim of establishing whether there are any function derangements associated with malnutrition this study will determine the short- (7 days) and long- (12 weeks) term effects of oral iron on attention, learning and memory among preschool children. It will be carried out in the Pacific lowlands of rural Guatemala with three groups of preschool children who differ in their body iron status (as indicated by hemoglobin status) as follows: Hgb greater than 11.5 gms.%; (2) 10 less than Hgb less than 11.5; (3) 8 greater than Hgb greater than 10. A secondary purpose is to obtain epidemiological data on zinc nutrition, lead poisoning and morbidity among the same sample of children.

A first screening of the hematological conditions of 96 children between 3 and 6 years of age where the study will be conducted has been already completed. Prevalence data indicate a high number of both moderate and severe cases of sideropenia. A behavioral pilot study in villages near where the study will be conducted has also been completed to determine the cultural fitness of the psychological tools to be used.

Research will use a prospective before- and after-treatment design (including placebo) with six subgroups of children of equal size matched on sex, age, anthropometry and SES. Assignment of the two subgroups within each of the three hematologic conditions will be randomized. Behavioral data will be collected before initiation of treatment, after short- and long-term treatment. Intra-individual and inter-individual comparisons will therefore be made in data analysis. Data collection includes clinical and anthropometric measurements; biochemical and hematologic determinations; and behavioral evaluations. Behavioral tests are selected from a theory that differentiates structural from process features of cognition.

ROLE OF HUMAN MILK IN INFANT NUTRITION AND HEALTH

R.R. Howell, University of Texas, Health Science Center at Houston, School of Medicine, Dept. of Pediatrics, *Box 20036, Houston, Texas* 77025 (P01 HD 13021-01)

This Core Section proposal describes the advantages which will accrue to the investigations which are components of this Program Project application. The 7 component projects are directly linked by virtue of common human milk donors and samples. Included in this Core Section are descriptions of (1) the logistics of sample collection, (2) the acquisition of a demographic data base for subsequent correlation with results of various assays to be performed on the milk samples (as well as other tissues), and (3) a shared computer-based system of data collection, storage, and analysis. The epidemiologists, computer programmer, and nurse specialists will function as core resource workers for all investigators included in this Program Project.

SMOKING, NUTRITION, SOCIAL CLASS, AND PERINATAL LOSS

D. Rush, Columbia University, School of Public Health, Dept. of Pediatrics, *600 W. 168th St., New York, New York* 10032 (R01 HD 13370-01)

We have observed more intense effect of smoking on perinatal mortality with decending social status (Rush and Kass, 1972). In a recently completed randomized controlled trial, nutritional supplements in pregnancy completely protected against the low birth weight associated with heavy maternal smoking in a deprived, public clinic population.

The first objective of this research is to explore further, among these heavy smokers, the effects of the nutritional trial on other outcomes of pregnancy, including placental structure and function, and newborn and one year old growth and development, particularly psychological function.

The second objective is to test whether the data of four large surveys of Pregnancy (The 1958 British Perinatal Mortality Survey, The 1970 British Births Study, The Cardiff Births Survey, and The Jerusalem Perinatal Study) support the possibility of nutritional mediation of the more intense effect of smoking with descending social status. Depressed maternal weight and/or weight gain in pregnancy have sometimes been associated with smoking, and sometimes not. The hypothesis that nutritional effects are linked with social status could explain these seemingly contradictory observations.

The contribution of smoking to the social class gradient of perinatal outcomes will be quantified. Next, we will study the extent of potentation of the effect of smoking by low maternal weight and/or weight gain. We will then judge whether the effect of smoking on the fetus is in part mediated by lowered weight and/or weight gain, and whether this path in part accounts for the interaction of smoking and social class on perinatal outcome.

These studies are meant not only to improve our understanding of smoking in pregnancy, but to elicit possible strategies for prevention.

THIRD INTERNATIONAL CONGRESS OF TWIN STUDIES

W.E. Nance, Virginia Commonwealth University, School of Basic Sciences & Graduate Studies, Dept. of Human Genetics, *901 W. Franklin St., Richmond, Virginia* 23284 (R13 HD 13561-01)

This grant will support the scientific program of the Third International Congress of Twin Studies which will be sponsored by the International Society for Twin Studies in Jerusalem, Israel, in June, 1979. Symposia, workshops, meetings for contributed and invited papers, and a poster session are planned. Topics to be discussed include the biological, epidemiological, psychological, and genetic aspects of the twinning phenomenon as well as methodological and statistical aspects of the use of twins for biomedical research. Examples of applied research in the areas of birth defects, behavior genetics, pharmacogenetics, cardiovascular disease, cancer genetics, and obstetrical care will be presented and the proceedings of the Congress will be published to make them accessible to the general biomedical community.

Twin studies have always played a major role in the genetic analysis of complex human traits. As increasingly sophisticated methodologies are developed and new phenotypes are examined, twin studies promise to assume an even greater importance during the next two decades as an efficient means of resolving genetic, environmental and maternal effects in man and for testing specific therapeutic hypotheses. The International Society for Twin Studies, through its publications and Congresses, can facilitate the realization of these potentialities.

2.0999,

RESPIRATORY FUNCTION DURING SLEEP, AND RISK FOR SIDS

C.T. Hoppenbrouwers, University of Southern California, Los Angeles County General Hospital, *3551 University Ave., Los Angeles, California* 90007 (R01 HD 13689-01)

The general objective of the proposed study is to improve ability to identify infants at increased risk for SIDS. Our study plan consists of identification of risk groups, based on current epidemiologic and physiologic data, as subsequent siblings of SIDS, 'near miss' for SIDS, premature infants born to teenage mothers and controls. We will study the infants longitudinally during the ages of highest risk for SIDS to detect developmental patterns. We will focus on cardiorespiratory variables during sleep states since respiratory control mechanisms vary with sleep state. Oxygen levels will be continuously recorded during monitoring sessions because the ultimate significance of altered breathing patterns depends on their effect on blood gas level. Specific variables of respiratory rate, heart rate, apnea, asynchronous breathing will be examined in relation to risk for SIDS, age and sleep state. Each variable has been selected because it should provide support for the hypoxia model for risk for SIDS. In infants with selected abnormal respiratory patterns, pulmonary function studies will be performed in order to clarify the underlying mechanisms.

2.1001,

THE GEOGRAPHIC VARIATION OF FETAL AND INFANT MORTALITY AND LOW BIRTH WEIGHT IN THE UNITED STATES, 1969-1974

C.A. Keller, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Child Health & Human Development, Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 HD 00304-02 EB)

The assembly of a large number of variables, including pregnancy outcome, has provided data on the marked variability in infant and fetal mortality among different populations in the U.S. The correlation of adverse pregnancy outcome rates with environmental variables will make it possible to assess the relative importance of the various factors associated with these rates in a large population. These data will also provide a basis for the assessment of changes in infant and fetal mortality which may be occurring in some populations.

STUDIES BASED ON THE MEDICAL BIRTH REGISTRY OF NORWAY, 1967-1973

H. Hoffman, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Child Health & Human Development, Biometry Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 HD 00801-04)

These studies have focused on: (1) the relation of the quality of medical care to the risk of perinatal death in Norway, (2) the tendency to repeat similar birth weight and gestational age in subsequent pregnancy outcomes to the same mothers, and (3) perinatal mortality in relation to order of birth and size of sibship.

BIBLIOGRAPHIC REFERENCES: Bakketeig, L.S., Hoffman, H.J. and Sternthal, P.M.: Obstetric service and perinatal mortality in Norway. 2.1003,

THE EFFECT OF ILLEGITIMACY ON INFANT MORTALITY FROM LINKED BIRTH-DEATH RECORDS IN MINNESOTA, 1967-1973

C.A. Keller, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Child Health & Human Development, Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 HD 00305-02 EB)

Illegitimacy has often been implicated as a risk factor in infant mortality. An analysis of linked birth-death records from Minnesota which allows information from birth certificates to be related to infant death rates, has indicated that among very young women, in whom most illegitimacy occurs, marital status is not a risk factor for early neonatal mortality, but may be for post-neonatal deaths.

2.1004,

THE SEASONALITY OF INFANT MORTALITY FROM LINKED BIRTH-DEATH RECORDS IN NORTH CAROLINA, 1967-1973

R. Nugent, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Child Health & Human Development, Epidemiology Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 HD 00306-02 EB)

The observed seasonality of neonatal deaths in the U.S. has implications as to the rule of environmental agents, e.g., infectious organisms, during pregnancy in influencing pregnancy outcomes. Since seasonality of conceptions may generate seasonality of neonatal death rates, linked birth-death records from North Carolina are being utilized to examine this relationship so that seasonality of death rates can be assessed independently of any seasonal variation in conceptions.

STUDY OF LINKED INFORMATION OF INFANT DEATH CERTIFICATES AND LIVE BIRTH CERTIFICATES FOR SELECTED U.S. STATES

H. Hoffman, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Child Health & Human Development, Biometry Branch, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 HD 00802-04)

The objective is to assemble a multi-state data file of infant deaths in which prior linkage with birth certificate information has been performed. The studies to be done on the data set include associations between infant (and fetal) mortality with the standard information on birth certificates (e.g. birth weight, gestational age, maternal age and race, parity, etc). These studies will be compared with similar studies on a 1950 and 1960 cohort of U.S. births. Additional comparisons will be linked data from Canada (1971), Great Britain (1970) and Norway (1976-1973).

OUTCOME OF SUCCESSIVE PREGNANCIES FOR NORWEGIAN WOMEN

L.S. Bakketeig, Universitetet i Trondheim, *7000 Trondheim, Norway, Norway*

Study the epidemiology of low birth weight and preterm delivery using the outcome of several successive pregnancies in a large population of women. Since the mother's identification number is recorded on the birth certificates, it is possible to retrieve medical information about consecutive births to the same mother. This system of data collection was begun in 1967, data is now available over a ten year span. This time period will provide a sufficient number of large sibships in order to examine the importance of familial tendencies for pregnancy outcome.

INITIATION OF HUMAN LABOR - PREVENTION OF PREMATURITY

P.C. MacDonald, University of Texas, Health Science Center at Dallas, Southwestern Medical School, Dept. of Obstetrics & Gynecology, *5323 Harry Hines Blvd., Dallas, Texas* 75230 (P50 HD 11149-03)

The objectives of this research are to define in the human fetus, amniotic fluid, fetal membranes, and uterine decidua the events that constitute a metabolic communication system, and to identify those fetal maturational events which initiate human parturition. We propose that the initiation of parturition is a consequence of fetal brain maturation, pituitary-fetal adrenal secretory processes and altered progesterone metabolism in fetal membranes; that lysosomal phospholipase A2, in fetal membranes and uterine decidua catalyzes release of arachidonic acid from glycerophospholipids in these tissues; and that free arachidonic acid is converted by the prostaglandin synthetase complex to prostaglandins and related compounds which facilitate myometrial contraction. We propose to investigate the ontogenesis of the human hypothalamic-pituitary vasculature, the ontogenesis of the subcellular compartmentalization of hypothalamic hormones, and the control of secretion of pituitary hormones; to identify the factors controlling growth and steroidogenesis of the fetal adrenal; to elucidate steroid hormone synthesis and metabolism in the placenta, fetal membranes, and uterine decidua; to characterize the subcellular localization of phospholipase A2 in fetal membranes and uterine decidua; to eluciate the biogenesis and regulation of prostaglandin and prostaglandin-related substances in the initiation of labor; to characterize the distribution of progesterone in fetal membranes throughout gestation; and to determine the role of fetal progesterone binding protein in the intracellular distribution of progesterone and in the metabolism of lysosomes. We will assess the epidemiologic factors of prematurity and develop a regional perinatal program for identification of gravidas at risk of prematurity. We will evaluate the impact of uteroplacental perfusion of therapeutic regimens used in preventing or arresting premature labor, and attempt to define the metabolic aberrations that cause premature labor.

PERINATAL INFECTIONS, IMMUNITY AND MALDEVELOPMENT

C.A. Alford, University of Alabama in Birmingham, School of Medicine, Dept. of Pediatrics, *1919 7th Ave. S., Birmingham, Alabama* 35233 (P01 HD 10699-03)

The major objective of the program is to study the natural history of perinatal cytomegalovirus (CMV) and group B Streptococcal infections in mothers, infants and children by large scale, prospective and longitudinal investigations. The CMV studies include in the mothers: 1) the role of recurrent versus primary infection in intrauterine and intrapartal transmission; 2) mechanisms of fetal transmission with recurrent maternal infection; and 3) effect of pregnancy hormones on growth of CMV. In infants and children they include studies on: 1) long term developmental outcome, 2) assessment of immunologic assays for detection of silent infection in the newborn, 3) pathogenetic studies of severe disease, and 4) nature of immune complex formation in congenital CMV. In addition, longitudinal studies of the humoral and cellular immune response in the maternal, congenital and natal infections are to be determined and related to virologic and clinical parameters over time and human strains are to be genetically analyzed and related to the disease state in man to search for microbial virulence factors.

The group B Streptococcal studies include prospective and longitudinal epidemiologic studies of strain specific colonization of mothers and infants and the role of the bacteria in both infectious and non-infectious complications of pregnancy. Modes of transmission from mother to baby and hospital spread will be sought. Serologic assays for detection of antibody will be developed and along with current assays compared for utility in investigating pathogenesis. In sick infected infants, bacteriologic and immunologic studies will be performed to better understand the early and late onset forms of group B infections to better define the pathogenesis of the two disease states in hopes of developing better therapeutic or preventive approaches in the future.

Both the CMW and streptococcal studies are to be integrated for correlative analyses in situations where deemed pertinent.

CORE PROGRAM FOR MENTAL RETARDATION RESEARCH

P. Dignan, Childrens Hospital Medical Center, *3245 Burnet Ave., Cincinnati, Ohio* 45229 (P30 HD 05221-10)

The Institute for Developmental Research (IDR) is devoted to research related to human development which may assist in finding causes and means of prevention of mental retardation or in finding means of ameliorating the effects of mental retardation. The IDR is a part of the Children's Hospital Research Foundation. By its close affiliation with many of the Children's Hospital Medical Center's Research Divisions, University Affiliated Facilities, and other hospitals and clinics the IDR, in addition to its own research program, enhances and stimulates mental retardation research in the entire Children's Hospital Medical Center and in other Departments of the University of Cincinnati College of Medicine.

PROGRAM FOR THE DEVELOPMENT OF THE MENTALLY RETARDED

R.K. Eyman, University of California, Los Angeles Campus, Neuropsychiatric Inst., Dept. of Psychiatry, *760 Westwood Plaza, Los Angeles, California* 90024 (P01 HD 05540-08)

The proposed research will investigate the effects of residential and educational environments on four sets of outcome variables as they relate to the mentally retarded: (a) mortality and the development of adaptive behavior, (b) personal-social development, (c) cognitive development, and (d) school and home adaptation. The research is based on rigorous investigation of the impact of two powerful and pervasive forces in the provision of services for mentally retarded persons - the principles of normalization and mainstreaming. In addition, the longitudinal study of mortality and changes in adaptive behavior for a five- to ten-year period is suggested to discern developmental trends on a large population of mentally retarded individuals from a number of states.

Four interrelated projects are proposed, each of which has its own specific aims, methods of procedure, and significance. All of them relate to the basic model, and all have as their ultimate objective the discovery of ways to improve retarded individuals' adaptation to their environments.

MENTAL RETARDATION RESEARCH PROGRAM

C.F. Barlow, Childrens Hospital Medical Center, *300 Longwood Ave., Boston, Massachusetts* 02115 (P30 HD 06276-08)

This program-project requests CORE and implementation support for broadly based program for the study of mental retardation and related aspects of human development. The scientific base for the pro-

gram rests upon investigation in three major areas: (a) Genetics and Metabolism; (b) Neuroscience; (c) Behavioral Science; all converging on a fourth area, (d) Clinical Studies of the Human Subject. The methodological and philosophical approaches include the clinical disciplines of pediatrics, neurology, neurosurgery, radiology, psychiatry, psychology, ophthalmology, otology and the basic science disciplines of pathology, physiology, pharmacology and biochemistry. The program is housed in five floors of the Pediatric Sciences Building.

The objective of the program is to provide a scientific and clinical base for the better understanding of the factors leading to mental retardation and to apply this information to prevention of the disorder, and management of the mentally handicapped individual.

A PROGRAM OF RESEARCH IN POPULATION CYTOGENETICS

P.A. Jacobs, University of Hawaii System, Manoa Campus, John A. Burns School of Medicine, Dept. of Anatomy & Reproductive Biology, *2444 Dole St., Pacific Biomedical Res. Ctr., Honolulu, Hawaii* 96822 (R01 HD 07879-06)

Utilizing material from spontaneous and inevitable abortions and their parents and from mentally retarded males we will determine: (1) the origin of the additional chromosome in trisomics, the additional haploid set in triploids and the mutation in structural aberrations by the use of chromosome heteromorphisms; (2) whether age-related somatic non-disjunction is correlated with meiotic non-disjunction as measured by the production of trisomic conceptuses; (3) the contribution of chromosome aberrations and ABO blood group incompatibility to fetal wastage and the practicality of using spontaneously aborted fetuses for population surveillance for mutagens and teratogens; (4) the cytogenetic status of trophoblast disease; (5) the relationship of race and social class to the epidemiology of trophoblast disease; (6) whether the source of the X-chromosome is related to its activation or inactivation and whether an active paternally derived X-chromosome in trophoblast plays any part in the genesis of trophoblast disease; (7) a method for enhancing the appearance of the abnormal X-chromosome in Renpenning's syndrome and the formal genetics and effect on retardation of the abnormal chromosome and its frequency among mentally retarded males.

2.1025,

STUDIES IN HUMAN GENETICS

B. Childs, Johns Hopkins University, School of Medicine, Dept. of Pediatrics, *725 N. Wolfe St., Baltimore, Maryland* 21205 (R01 HD 00486-25)

Three behavioral phenotypes are to be studied using a genetic-epidemiologic approach. 1) Phenotypic variations of specific reading disability will be characterized in subjects attending schools for learning disabled children, their sibs, parents and collateral relatives, and the hypothesis of phenotypic and genetic heterogeneity will be tested. The impact of reading disability on development and occupational choice will also be studied. 2) The hypothesis of genetic heterogeneity in schizophrenia will be tested by contrasting the phenotypic properties of patients with preadolescent and early adult onset with those of later onset. 3) The psychiatric symptoms in patients with Huntington's disease and their 'at risk' children will be characterized.

MENTAL RETARDATION RESEARCH CENTER

G. Tarjan, University of California, Los Angeles Campus, Neuropsychiatric Inst., *760 Westwood Plaza, Los Angeles, California* 90024 (P30 HD 04612-11)

This proposal provides central support for Research in Mental Retardation at UCLA. The Mental Retardation Research Center at UCLA is a multi-funded, interdisciplinary research and teaching program which has the following objectives: 1. Research into problems of mental retardation and related aspects of human development. 2. Research training, at the pre- and post-doctoral levels, of specialists in a variety of disciplines related to our goals.

Studies fall into the following categories: Developmental Biology, Neurophysiology, Neurobiochemistry and Socio-Behavioral Research. Most of our research efforts are carried out on the UCLA campus. Additionally, a large multi-disciplinary research program exists at the Pacific State Hospital (recently renamed Lanterman State Hospital) in Pomona, California.

2.1027,

PREGNANCY AND DES ASSOCIATED UPPER GENITAL ANOMALIES

R.H. Kaufman, Baylor College of Medicine, School of Medicine, Dept. of Obstetrics & Gynecology, *1200 Moursund Ave., Houston, Texas* 77025 (R01 HD 10989-03)

The investigators intend to assess the prevalence of upper genital tract anomalies in women exposed in utero to diethylstilbestrol. They will relate the changes found in the upper genital tract to those found in the lower genital tract. In addition, they will attempt to evaluate the incidence of pregnancy wastage in relation to upper genital tract anomalies found in these individuals.

In addition, they will attempt to evaluate the prevalence of urinary tract anomalies that may or may not co-exist with genital tract anomalies found in the DES exposed offspring.

2.1028,

DEVELOPMENTAL EFFECTS OF LOW LEVEL LEAD EXPOSURE

H.L. Needleman, Childrens Hospital Medical Center, *300 Longwood Ave., Boston, Massachusetts* 02115 (P01 HD 08945-04A1)

This Program Project Grant proposes to extend our studies of low level lead exposure in children and experimental animals to address the following questions: 1) Does prenatal exposure to lead affect outcome at birth and later in life? 2) Does lead exposure have long delayed effects related to aging or late neurologic disease? 3) Does chelation prevent demonstrated changes in synaptic maturity and dendritic complexity?

Epidemiologic studies of gravid women and their offspring in which lead is the risk factor will conducted, treating birth outcome and later development as outcome variables.

Animal models of controlled lead exposure will be employed to test the same hypotheses under experimental conditions. Animals will be given controlled amounts of lead at varied periods of gestation, and offspring studied for ultrastructural changes in brain, distribution of lead by radiosotopes, and behavioral change by quantitative techniques. The effects of chelation on outcome will also be studied.

2.1029,

NEONATAL GROUP B STREPTOCOCCAL INFECTIONS

S.P. Gotoff, Michael Reese Hospital & Medical Center, Dept. of Pediatrics, *2929 S. Ellis Ave., Chicago, Illinois* 60616 (R01 HD 09700-03)

We have developed a fluorescent antibody technique for rapid identification of group B streptococci in human specimens. The technique has a sensitivity of 52% for detection of maternal vaginal colonization within 6 hours of culture; 93% after overnight (greater than 18 hours) incubation. The FA technique is being used as a semiquantitative method of assessing the risk of vertical transmission of group B streptococci from parturient women to their newborn infants.

Using biologic characteristics of group B streptococci which permit specific identification of strains (serotype, antibiogram, neuramindase production, chick embryo virulence, and bacteriophage type we are studying nosocomial transmission in a high-risk nursery environment.

Using the risk factors of premature labor and prolonged rupture of maternal membranes as criteria for selection, we are conducting a controlled study of ampicillin prophylaxis of neonatal group B streptococcal infections in colonized women in labor.

DIPLOCOCCUS PNEUMONIAE - INFECTION AND IMMUNITY

H.C. Dillon, University of Alabama in Birmingham, School of Medicine, Dept. of Pediatrics, *1919 7th Ave. S., Birmingham, Alabama* 35233 (R01 HD 09732-04)

The natural history of Str. pneumoniae infections is being studied in a group of infants now 3-4 years of age, who have been followed since birth. The relation between pneum coccal carriage, infection and immunity is being determined in prospective fashion. Pneumococci are serotyped with Danish reference antisera. Antibody is determined in this laboratory by NBT assay and by a newly developed ELISA method. Collaborative arrangements with Dr. Gerald Schiffman provide for antibody assay by the RIA technique. In addition to patients prospectively investigated, seroepidemiologic studies are being performed, utilizing sera for children and adolescents stored from prior investigations. Included in the latter are sera from patients with well-defined pneumococcal infections. including otitis media and bacteremia. Comparative epidemiology of pneumococcal infections in children and adults is investigated by examining collections of clinically relevant pneumococci from pediatric and adult infectious disease services. Host age range, clinical syndrome, serotype causing disease, serological response to infections and seasonal trends of pneumococcal disease are being determined.

2.1031,

CYTOMEGALOVIRUS - TRANSMISSION TO NEWBORNS BY BLOOD

A.S. Yeager, Stanford University, School of Medicine, Dept. of Pediatrics, *Stanford, California* 94305 (R01 HD 09872-04)

The purpose of the proposed investigation is to determine whether the risk of transfusion-acquired Cytomegalovirus (CMV) infections to premature infants can be decreased by the use of donors who have no measurable antibody to CMV as assessed by a modified hemagglutination inhibition (IHA) assay. A simplified method of performing the IHA test will be compared to indirect fluorescent antibody methods as regards sensitivity and evaluated for suitability for use in a blood bank. Assessment of host factors which may correlate with the severity of symptoms in infected babies and with the amount of virus excreted will include measurement of maternally derived antibody, evaluation of the onset of production of CMV IgM antibody, enumeration of T, B and monocyte cells, CMV and PHA lymphocyte stimulation assays and CMV and HSV interferon production. Pulmonary and hepatic function and platelet levels will be measured in infected babies. The influence of infection on the length of time of assisted ventilation and O2 administration, rate of weight gain and length of hospital stay will be evaluated. At 1, 2, and 3 years of age infected infants will have tests of hearing, vision, neurological and intellectual function. The results will be compared with uninfected controls. The transmission patterns in seronegative members of families of infected babies will be studied in an effort to evaluate the risk of transmission from infect-

ed babies to seronegative mothers during a subsequent pregnancy.

CLINICAL CORRELATIONS TO VITAMIN D STATUS IN INFANTS

L.S. Hillman, Washington University, School of Medicine, Dept. of Pediatrics, *660 S. Euclid Ave., St. Louis, Missouri* 63110 (R01 HD 09998-03S1)

The object of this grant is to study a number of problems in infants which may be related to 25-hydroxyvitamin D (25-OHD) deficiency: 1) early neonatal hypocalcemia, 2) late neonatal hypocalcemia, 3) rickets and severe osteopenia, 4) Sudden Infant Death Syndrome (S.I.D.S.) and 5) dental hypoplasia. Laboratory determinations and x-rays obtained during the first 3 months of life are to be further correlated with long term growth and development. 73 premature infants, 34 SGA infants, and 8 IDM infants have been enrolled in the study and been prospectively followed. Additional post-mortem samples have been obtained from 23 SIDS and 7 control infants. 8 near-missinfants and 6 infants with late neonatal hypocalcemia seizures have been studied. Analysis of 25-OHD concentrations has been completed in 59 cases and calcium, magnesium, phosphorous and copper have been completed in 100 cases. During the third year, we will concentrate on getting good follow-up of those infants enrolled and obtaining complete dental examinations. We hope to complete analyses of all samples early in the year and begin to correlate laboratory, x-ray and clinical data within the first 3 months. We will also set up a system for analysis of follow-up data related to these earlier findings.

SEX CHROMOSOMAL ABNORMALITIES - A PROSPECTIVE STUDY

A. Robinson, University of Colorado, Medical Center, National Jewish Hospital & Research Center, *3800 E. Colfax Ave., Denver, Colorado* 80206 (R01 HD 10032-04)

The purpose of this research is to continue our study of a group of children with abnormalities of the sex chromosomes who were identified in a cytogenetic survey of 40,000 consecutive births from 1964-1974. This patient group offers the opportunity for study of genetic, developmental, physical and psychological factors in these complex conditions.

Our long-term objective is to define the ultimate prognosis for each of these conditions--47,XXX; 47,XXY; 47,XYY; 45,X and mosaicisms of these. Some, but not all, individuals with these karyotypes will have intellectual, emotional or social problems in later life. The data will be analyzed by comparisons between subgroups and by using normal siblings as controls. Previous study of this group of children makes it possible to focus the investigation during childhood on particular facets of vulnerability, and during adolescence on relative changes from previous growth, endocrine and behavioral status. By following the development and by therapeutic intervention, including endocrine where indicated later irreversible pathology may be prevented or ameliorated.

ETIOLOGIC ASPECTS OF SUDDEN INFANT DEATH SYNDROME

P.L. Ogra, Childrens Hospital of Buffalo, Dept. of Pediatrics/Microbiology, *219 Bryant St., Buffalo, New York* 14222 (R01 HD 10088-04)

The long range objectives of this proposal are to examine the microbiologic and immunologic aspects of host defense in sudden infant death syndrome (SIDS). The specific aims of this investigation conducted during the current budget period were 1) to examine the functional aspects of immunologic reactivity in the mucosal surfaces of the respiratory tract in SIDS and in normal healthy living neonates, 2) to determine the prevalence and nature of respiratory viral infections in this community relative to the occurrence of SIDS, and 3) to examine the immunologic and microbiologic status of infants with episodes of apnea.

SELECTED FACTORS INFLUENCING INCIDENCE OF ORAL CLEFTS

J. Niebyl, Johns Hopkins University, School of Medicine, Dept. of Obstetrics & Gynecology, *725 N. Wolfe St., Baltimore, Maryland* 21205

A study to determine the feasibility of studying high-risk mothers (mothers who have given birth to cleft children previously) with respect to potential environmental and metabolic etiological factors affecting their children prenatally and resulting in oral clefts. The final target of such research would be to identify a large-scale high-risk group of mothers and to reduce the risk by modifying prenatal circumstances. The first step in the development of a preventive program for congenital cleft lip and palate will be to identify likely etiologic factors and explore a small population to determine the needs and objectives of a larger study.

A WORKSHOP CONFERENCE ON METHODS OF CARIES PREDICTION

B.G. Bibby, Eastman Dental Center, Caries Research, *800 Main St. E., Rochester, New York* 14603 (R13 DE 04743-01)

Because of the absence of any accepted method for predicting caries, it is proposed to examine the procedures previously used for that purpose, and seek new approaches to the problem. For the latter purpose the nature of the variables recently described in studies of bacteria, saliva, food, tooth structure and caries initiation will be sifted for use as caries predictors. Task Forces representing the various biologic and epidemiologic aspects of caries will select, in their field of responsibility, the most promising approaches to practical caries prediction and indicate how these can be brought to a stage of clinical reliability. The conference papers, summaries of the discussion and the Task Force reports will be edited and submitted to Information Retrieval, Inc., for publication. Copies will be sent to all members of the American Association for Dental Research.

CENTER FOR CLINICAL RESEARCH IN PERIODONTAL DISEASES

S.S. Socransky, Forsyth Dental Center, Dept. of Periodontology, *140 Fenway St., Boston, Massachusetts* 02115 (P50 DE 04881-02)

To investigate the etiology of periodontal diseases, possible mechanisms of tissue destruction, and the effects of therapeutic measures, a series of clinical experiments have been designed in which the interrelationships between composition of the plaque microbiota, immunologic response and potential mediators of local tissue pathology are studied in a patient population with advanced destructive disease. Extensive clinical measurements will be carried out to verify that each patient is in an active state of disease at the time of investigation and to monitor the effectiveness of therapeutic regimens tested. Local levels of administered agent will be assessed by pharmacologic monitoring in order to verify that effective dosage has been achieved. Clinical disease activity will be correlated with parameters measured in the laboratory in order to seek possible laboratory aids to diagnosis.

The patient's immunologic response to his or her own microbial populations will be tested. By determining which organisms are eliminated or suppressed by different therapeutic regimens and monitoring disease activity, it is hoped that specific pathogens responsible for active periodontal disease can be identified. These findings should lay the basis of preventive therapy directed toward elimination of specific pathogens. By determining the nature of the host response to resident organisms, it is hoped that a more precise definition of pathogenic mechanisms will be obtained which will direct efforts seeking alternative therapeutic measures. By determining the clinical effect of various forms of periodontal therapy, it is hoped that more rational approaches for treating periodontal disease will be devised.

At this time, few definitive tests are known which can be used to guide therapy, or to assess its effect. By thoroughly investigating the multiplicity of interrelated facts which are associated with the periodontal disease process, it is hoped that bases for rational prevention and therapy will be established.

2.1039,

NOCTURNAL MASSETER MUSCLE ACTIVITY AND JAW DYSFUNCTION

G.T. Clark, University of California, Los Angeles Campus, School of Dentistry, Section of Gnathology & Occlusion, *405 Hilgard Ave., Los Angeles, California* 90024 (R23 DE 05036-02)

The objective of this study is to investigate the specific relationship between nocturnal masseter muscle activity, and the signs and symptoms of abnormal jaw muscle function in normal subjects and subjects with myofascial pain.

The methods of this project include using a portable cummulative EMG device to establish the average level of masseter muscle activity over a two week period during normal sleep. A measure of the maximum bite force and a measure of the subject's fatigability and his kinesthetic sense will be performed. These measures will be performed on approximately 40 subjects with the absence of any subjective symptoms of jaw dysfunction and in 60 patients who complain of abnormal jaw muscle function but have no TMJ intracapsular dysfunction. An epidemiologic type index will be used to score and evaluate the symptoms of dysfunction along with the occlusal characteristics on all subjects. These subjects will be directed towards establishing levels of nocturnal muscle activity and measures of jaw muscle function in normal and symptomatic subjects. The symptomatic subjects will undergo 6 weeks of treatment

either with exercises or an occlusal splint and a followup post-treatment evaluation will be performed on all subjects.

In summary, it will be of interest to relate the amount of nocturnal masseter muscle activity to the signs and symptoms of jaw dysfunction. These measures of jaw muscle function will serve as pretreatment records so that any change may be examined for and compared after routine treatment for myofascial pain. This information will hopefully answer the following two questions: 1) 'Is there a constant relationship between nocturnal muscle activity, abnormal jaw muscle function and the symptoms of myofascial pain dysfunction, and 2) what effect does occlusal splint therapy vs. exercise-heat therapy have on this relationship, if any.

BIBLIOGRAPHIC REFERENCES: Clark, G.T., Beemsterboer, P.L., and Bell, G.: The effect of jaw muscle fatigue on mandibular kinesthetic ability. J. Dent. Res. AADR abstract #991, 1980. GENETIC CONTROL OF SUSCEPTIBILITY TO CLEFT PALATE

M.L. Tyan, University of California, Los Angeles Campus, School of Medicine, Dept. of Medicine, *2025 Zonal Ave., Los Angeles, California* 90024 (R01 DE 05165-01)

Evidence suggests that an increased incidence of cleft palate may be associated with HLA-A2, a major histocompatibility complex antigen. If this is true then HLA antigens can be used as genetic markers for increased susceptibility to cleft lip and/or palate. The proposed studies have been designed to confirm the HLA/cleft palate association. Cooperating institutions throughout the Los Angeles Metropolitan area will provide subjects to be HLA typed. About 1,100 patients will be available. All HLA typing of experimental and control populations will be done by the UCLA HLA typing facility directed by Dr. P.I. Terasaki. A sample of blood containing live cells and a sample of serum from each patient will be preserved in liquid nitrogen for future use. The identification of genetic markers for cleft lip and/or palate susceptibility will lead to the development of procedures to reduce the incidence of these craniofacial anomalies.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Dental Research $75,084

2.1041,
THE EFFECT OF SCHOOL WATER FLUORIDATION ON DENTAL CARIES

S.B. Heifetz, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Dental Research, Community Programs Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 DE 00029-12 CPR)

Fluorides were added to the water supply of a school in Seagrove, North Carolina. The concentration of fluoride used was higher than the level considered optimal for community water fluoridation in the geographic area. Children attending the Seagrove school live in an area without a central water supply and where the various sources of well water contain negligible levels of fluoride. Children are exposed to the higher fluoride level only while at school in an attempt to approximate the total fluoride intake of children who drink optimally fluoridated water on a full-time basis. Baseline dental examinations for dental caries were made prior to the installation of fluoridation equipment. Follow-up examinations are conducted after four, eight, and twelve years to determine the extent of caries protection as increasingly larger segments of the study population become continuously exposed to fluoridated water at school since entering the first grade. Results of the four-year examinations showed appreciable decreases in caries prevalence compared with baseline findings. On the eight-year examinations, an assessment of the prevalence of dental fluorosis was made along with the regular examinations for dental caries. No children showed any definite signs of the condition. NIDR Classification: 10550.

BIBLIOGRAPHIC REFERENCES: Heifetz, S.B., Horowitz, H.S., and Driscoll, W.S.: Effect of school fluoridation on dental caries: results in Seagrove, N.C. after eight years. J. Amer. Dent. Assoc. 97:193-196, 1978.

PERIODONTAL DISEASE IN INDIVIDUALS WITH JUVENILE DIABETES AND DOWN'S SYNDROME

L. Cianciola, State University of New York, Health Science Center at Buffalo, School of Dentistry, Dept. of Oral Biology, *3435 Main St., Buffalo, New York* 14214 (P50 DE 04898-020009)

Juvenile periodontal disease involving alveolar bone loss seem to be rapidly destructive by nature. When this form of periodontal disease affects a compromised host, as the juvenile diabetic or the Down's patient, it seems to be even more aggressive. Localized juvenile periodontitis may progess into generalized juvenile periodontitis at a very rapid rate. The periodontal status of the juvenile diabetic has not been fully described, and the incidence of periodontal disease in the juvenile diabetic and the Down's patient has not been fully determined. The purpose of the present investigation is to cross sectionally and longitudinally study both the juvenile diabetic and Down's patient for the incidence, age of onset, and rate of progression of periodontal disease. The periodontal status of these patients is determined both clinically by a plaque, gingival and calculus indices and radiographically. Study patients are compared to randomly selected matched control subjects in whom similar measurements are made. Correlation of neutrophil functional analysis and severity of periodontal disease will be carried out in the patients with juvenile diabetes. In addition, periodontitis and other dental infections will be monitored in juvenile diabetics in ketoacidosis.

SUPPORT FOR ORAL BIOLOGY RESEARCH CENTER

R.C. Page, University of Washington, School of Medicine, Dept. of Pathology, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (P50 DE 02600-13)

This proposal seeks continued support for the development and continuation of an interdisciplinary Center for Research in Oral Biology. The central goal or purpose of the Center is to assist in the national effort to reduce the toll of oral disease and to promote the general level of oral health. The Center is achieving this goal by developing and supporting meritorious and relevant research projects, by creating an intellectual and physical environment conducive to optimal research productivity, by providing opportunities for significant interaction between investigators with diverse backgrounds, by producing both basic and applied knowledge related to the oral region, and by encouraging the incorporation of relevant research findings into dental education, dental practice, and the surrounding community. The types of projects supported have been the subject of intensive discussion within the Center and by the Scientific Review Committee, and within the committee appointed by the Vice President for Health Affairs to study the future pattern of the Center. The emphasis in the past has been on high quality basic research programs. This emphasis continues, but we are increasing our percent effort directed toward application of basic research findings to problems of patient diagnosis and care and to measures which will lead to improvement of the oral and dental status of the population.

2.1045,
CENTER FOR ORAL HEALTH RESEARCH

H.M. Myers, University of Pennsylvania, School of Dental Medicine, Dept. of Microbiology, *4001 Spruce St., Philadelphia, Pennsylvania* 19104 (P50 DE 02623-11)

The principal aims of the Center are to gather and prepare research personnel to investigate and to determine fundamental information on the development, the structure and the function of human oral tissues and associated structures as well as the microbial parasites which are present on or in the tissues in health and disease. The Center will place particular emphasis on research workers who are interested in collaborative efforts with scientists in the University Community. It is to be expected that new investigators, both established and those with promise, will be attracted by the work in progress. In this manner, it is hoped that the 'work force' in oral health research will be increased and thus eventually provide improvements in the maintenance of oral health and in the measures for prevention of oral disease. The work in progress is concerned with the metabolic activities of specific oral microbes involved in dental caries; differentiation of oral streptococci by analysis of the structural components of the cells, analysis of the protein antigens of herpes simplex virus; an epidemiologic study of oral manifestations of herpes simplex infections; studies of the ultrastructure of periodontal tissues; and studies on the immunologic responses of oral tissues.

REGIONAL DENTAL RESEARCH CENTER

P.F. Hirsch, University of North Carolina, Chapel Hill Campus, School of Dentistry, Dept. of Pharmacology, *Chapel Hill, North Carolina* 27514 (P50 DE 02668-13)

The program of research is targeted to establish new approaches to oral health research through the development of an interrelated and cohesive research program, involving highly qualified personnel, trained in various basic sciences. The inclusion of non-dental scientists recruited from other research fields emphasizes an interdisciplinary approach for collaboration within specified areas of research interests. These include neural mechanisms, mechanisms of mineralization, immunological mechanisms, growth mechanisms, biomaterials research and problems of hemostasis, as well as applied clinical research in oral-facial pain control, restorative materials, and habilitation of patients with craniofacial anomalies. The overall objective of the program is to bring together scientists with diverse backgrounds in collaborative research efforts to relative to growth, development and function of the craniofacial region. Developing new manpower to broaden and strengthen the scientific base to improve oral health is achieved by our non-dental investigators and through an active research training program. Further objectives are to utilize effectively the scientific strengths of the entire University and neighboring regional resources and to involve an appreciable number of the Institute staff as active members of academic departments in the University.

STUDY OF CRANIOFACIAL ANOMALIES

S. Pruzansky, University of Illinois, Medical Center at Chicago, Abraham Lincoln School of Medicine, Dept. of Pediatrics, *1853 W. Polk St., Box 6998, Chicago, Illinois* 60680 (P01 DE 02872-10)

The Center for Craniofacial Anomalies of the A. Lincoln School of Medicine of the University of Illinois Medical Center at Chicago is a multidisciplinary organization that provides comprehensive care for patients with congenital, developmental and acquired malformations. The Center contributes to special training programs in the health sciences and conducts clinical and laboratory research. The major research thrust is a continuing longitudinal growth

study to study the natural history of various malformations. The data base includes case histories, photos, study casts, cephalometric and tomographic radiographs, audiometric and speech records on nearly 5000 subjects. Current projects focus on the epidemiology and genetics of congenital palatopharyngeal incompetence and hemifacial microsomia. Early treatment of serous otitis in children with cleft palate is being investigated under controlled conditions. Results of craniofacial surgery for orbital hypertelorism, Apert and Crouzon syndromes, hemifacial microsomia, and mandibulofacial dysostosis are evaluated in terms of subsequent growth and functional studies involving eye motility, vision, speech and hearing. Screening programs are underway to determine the frequency and type of cardiac anomalies; frequency of ophthalmopathy in patients at risk for retinal detachment (Robin and Stickler syndromes). Clues derived from clinical investigation have led to electronmicroscopic studies in ectodermal dysplasia and abnormalities of mucopolysaccharide metabolism in cleft palate and Apert syndrome in an effort to elucidate pathogenetic mechanisms.

A CASE-CONTROL STUDY OF PROSTATE CANCER WITHIN A COHORT OF RUBBER AND TIRE WORKERS

D.F. Goldsmith, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514 (1-T32-ES070 36-01)

OBJECTIVE: To identify the specific occupational groups associated with prostate cancer excesses, and to estimate a latency period for the tumor among the cohort of rubber and tire workers.

APPROACH: A matched case-control study was conducted to test the hypothesis that prostate cancer is associated with employment in the compounding area of a rubber and tire manufacturing plant. A search of death certificates from the years 1964-75 led to the identification of 88 cases of prostate cancer. These were individually matched with 258 controls on the factors of age, race, and date of entry into the plant. To eliminate possible confounding by sociodemographic differences, several variables were assessed but none differed.

PROGRESS: The Batch Preparation work area showed statistically significant (P less than .025) risk ratios over three exposure periods longer than 1 month, longer than 24 months, and longer than 60 months. The Service to Batch Preparation and Shipping and Receiving work areas showed significant risks for blacks.

The data were used to assess a latent period or etiologic fraction for prostate cancer for those employed in Batch Preparation. Twenty-nine years was estimated to be the latent period while the period of greatest risk occurred during the years 1940-47.

STUDY OF EFFECT OF ASBESTOS FIBERS ON TISSUES

T.R. Hamilton, University of Minnesota, Duluth Campus, School of Medicine, Dept. of Pathology, *2400 Oakland Ave., Duluth, Minnesota* 55812

Collect biologic samples, both human and non-human, which assure broad biologic sampling of the population exposed to Duluth's drinking water. Materials to be collected will include urine, feces, blood, placent (placental blood), surgi- cal biopsy tissues, and autopsy tissues as feasible. Preserve and store samples in ways which ensure future usefulness and which ensure compatibility with preservation and storage methodology currently being employed by Dr. Selikoff and his colleagues. Collect and analyze appropriate radiographic materials of long-term Duluth residents. Secure requisitedescriptive information including good residential and occupational histories of all individuals included in the survey.

DEVELOPMENT OF IN VITRO MODELS FOR ASSESSING REPRODUCTIVE TOXICITY

J.L. Hall, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Germ Cell Toxicity Group, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 70085-02 LET)

Heterologous (human sperm/hamster egg) in vitro fertilization was used to assess fertilizing capacity of human males. These studies identified certain individuals as subfertile who have routinely determined normal sperm number, motility and morphology. This approach demonstrated that the usual parameters for semen analyses are unsure predictors of male subfertility; only the most extreme semen abnormalities reliably indicate subfertility. Thus, the in vitro penetration of laboratory animal ova by human sperm appears to be an improved technique to assess human fertilization potential. The epidemiologic application of this noninvasive, fast and relatively inexpensive technique is being explored.

DEMOGRAPHIC INVESTIGATIONS OF POTENTIAL HUMAN HEALTH HAZARDS

M.D. Hogan, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 43001-07 BB)

The overall objective of this project is to identify and/or confirm the presence of various potential health hazards in the general environment through the mechanism of demographic investigations. Current research activities are concerned with the development of quantitative estimates of both the extent of potential occupational exposure to asbestos since the World War II era and of its impact on current and future overall cancer mortality in the United States.

STUDIES IN PEDIATRIC LEAD EXPOSURE

W.J. Rogan, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 43003-1 BB)

Lead exposure and undue absorption occurs not only in inner city children exposed to paint but also in children around smelters and those whose parents work with lead. Although the encephalopathy and renal disease of acute lead intoxication are well described, other toxicities of lead as well as factors that alter susceptibility need further research. We have completed a pilot study on lead levels and blood pressure in children, and have begun investigation into genetic differences in susceptibility.

FETAL WASTAGE AND CHEMICAL EXPOSURE

S.M. Brown, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 44003-02 BB)

The objective is to examine the variations in response of pregnant women who are exposed to any of a number of defined environmental mutagens and clastogens. At the current time a survey instrument is being prepared under contract for interviewing mothers and fathers of spontaneous abortuses and controls in order to assess exposure in occupation, household, personal habits, or other vehicles. The disease outcomes of interest are spontaneous abortion, anatomic, or cytogenetic abnormality of fetal tissues.

2.1072,

NEUROTOXICOLOGICAL EFFECTS OF POLYBROMINATED BIPHENYLS IN RATS AND MICE

H.A. Tilson, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Behavioral Toxicology Group Section, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 70805-02 LBNT)

This is a completion report of work that was in progress at the time of the last reporting. Polybrominated biphenyls (PBB) have been recognized as an environmental hazard following the inadvertent mixture of PBB to animal feed. Rats and mice were tested after 30 days of dosing by gavage with Firemaster FF-1 (0.03-30 mg/kg), the major PBB component, or with corn oil vehicle, and 30 days after dosing ceased. Effects observed included decreases in body weights, open-field activity, forelimb grip strength, and muscular reflexes. Loss of visual placement and hypothermia were seen in some animals. FF-1 was generally more potent than HBB. Rats were more affected than mice. Rats did not recover as well (or worsened) relative to mice during post-dosing. The results suggest neurobehavioral deficits may be produced by PBB at levels lower than those which produce clinical signs of toxicity.

2.1073,

SKIN CANCER AND TRACE ELEMENTS

L. Clark, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 43004-1 BB)

The objective of this work is two-fold: first, to examine the hypothesis that there is a relationship between the etiology of skin cancer and the levels of certain trace elements in blood or hair. The elements of interest include selenium, arsenic, cadmium, zinc, copper, and lead. The issue relating to selenium is of the greatest interest. Second, the hypothesis that occupational exposure to herbicides, pesticides, or fungicides, including those containing arsenic as well as other groups of aromatic or aliphatic hydrocarbons, is a significant risk factor in the development of skin cancer, will be examined. A case-control study in which subjects from a specific dermatologic clinic practice in the eastern part of North Carolina is anticipated. Four groups of skin cancer patients of different types will be compared with a group of dermatologic controls (persons with skin disease other than, and unrelated to, skin cancer). The disease outcome of interest is skin cancer, and the risk factors of interest are selenium level, other trace element levels, and occupational exposure.

SUPPORTED BY U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences funds n.a.

2.1074,

REPRODUCTIVE EXPERIENCE OF DRYCLEANING WORKERS AND THEIR CONJUGAL/MARITAL PARTNERS

A. Wilcox, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 43005-01 BB)

The objective is to complete a feasibility study on the possibility of contacting a suitable number of female drycleaning workers who are members of a labor union in St. Louis, Missouri. This union has been under study for cancer mortality by the Environmental Epidemiology Branch at the National Cancer Institute. The effort of the feasibility study is to determine whether or not a sufficient sample of female workers is available and willing to cooperate in an interview survey of their reproductive experience. The major study of interest would focus on the current rate of spontaneous abortion and other reproductive outcomes including birth defects. A second issue under consideration is whether or not tissue samples of parents of fetuses should be studied for cytogenetic damage.

2.1075,

GENETIC EFFECTS, REPRODUCTIVE OUTCOMES, AND BIRTH DEFECTS AND OCCUPATIONAL EXPOSURE TO PLUTONIUM

S.M. Brown, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, Biometry Branch, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 43006-01 BB)

The principal objective is to examine the reproductive outcomes principally of spontaneous abortion but also congenital defects and perhaps childhood cancer among a cohort of females associated with five federal facilities in which there was significant occupational exposure to plutonium. The work will be performed in two stages. In the first stage, a cohort study of female workers at the five facilities is entertained. The protocol of that study is currently being planned. The second stage would study the same outcomes in the wives or conjugal partners of exposed male workers at these same facilities. An attempt will be made to ascertain the existence of a dose-response relationship, at least for the most common outcome (spontaneous abortion).

OCCUPATIONAL AND ENVIRONMENTAL HEALTH

J.L. Whittenberger, Harvard University, Cambridge Campus, School of Public Health, Dept. of Physiology, *Cambridge, Massachusetts* 02138 (P30 ES 00002-17)

This research and research training program emphasizes a variety of laboratory studies and epidemiologic approaches to the study of the effects of environmental and occupational factors on the health of man. Specific examples include the following: morphology and cytochemistry of lysosome formation in alveolar macrophages; effect of breathing pattern and lung volume on the distribution of inhaled radioactive particles; effect of inhibition or alteration of biotransformation; development and exploitation of differentiated mammalian cell culture systems to detect and examine the mechanisms of action, and develop means for prevention or reversal of certain environmental chemical toxic agents; development of new chemical and immunologic assay methods for certain classes of environmental chemicals; development and use of affinity probes to identify the sites and molecular mechanisms of action of specific toxic agents; experimental lung cancer; malignant transformation in vitro; cancer morbidity among rubber workers; mortality among Boston firefighters 1915-1975.

RESEARCH IN THE ENVIRONMENTAL HEALTH SCIENCES

N. Nelson, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016 (P30 ES 00260-17)

This grant provides core support for a broad program in the Environmental Health Sciences. The research under way and proposed is broadly relevant to adverse health effects from Environmental factors. The general objectives of the research are to define the nature and extent of such effects with the aim of instituting appropriate preventive or control procedures where required. Interests range from acute to chronic health effects including, in the latter, cancer and the degenerative diseases.

The research encompasses laboratory studies on the biochemical mode of action of environmental toxicants, exploratory studies aimed at improving the reliability and efficiency of predictive toxicological tests, improvement of diagnostic procedures for diseases possibly related to environmental factors, epidemiological investigations and field studies on the distribution of pollutants.

SURVEILLANCE OF POTENTIAL ENVIRONMENTAL HEALTH HAZARDS

T. Damstra, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Environmental Health Sciences, *P.O. Box 12233, Research Triangle Park, North Carolina* 27709 (Z01 ES 20004-05 OHHA)

The objectives of this long-term project are: (1) to compile an index of associations between organ system diseases and symptoms in human and exposure to environmental and occupational chemicals; and (2) to assess the practicality and validity of using neurological and behavioral tests as early indicators of toxicity and as surveillance 'tools'.

TOXICOLOGY OF ENVIRONMENTAL CHEMICALS

V.H. Freed, Oregon State Higher Education System, Oregon State University, School of Agriculture, Dept. of Agricultural Chemistry, *35th & Jefferson Sts., Corvallis, Oregon* 97331 (P01 ES 00040-15)

The research of this program grant involves long-term interdisciplinary studies of the toxicological effects of environmental chemicals. Fourteen investigators representing different disciplines direct projects on biochemical mechanisms of toxicity, oncogenesis, and effect on oncogenic viruses, pharmacodynamics, modeling, statistical methods for toxicology, biochemical effects, and physico-chemical relationships of routes and rates of exposure. Examples of the type of work conducted include investigation of effects of halogenated phenols on membranes, oncogenicity of halogenated hydrocarbons and interactions with other carcinogenic agents, covalent binding of toxicants and immunological effects of environmental chemicals. Other studies are directed toward elucidating the photochemistry of environmental toxicants, physico-chemical properties in relation to biological effects and behavior, and mathematical and statistical modeling of the dynamics and toxicological behavior of compounds. Among the compounds under investigation include halogenated phenols containing one to three aromatic rings heavy metals, ethyl nitrosourea, halogenated hydrocarbons, carcinogenic alkaloids, and several industrial and agricultural chemicals of environmental significance.

MECHANISMS OF PESTICIDE TOXICITY

E. Hodgson, University of North Carolina, North Carolina State University, School of Agriculture & Life Sciences, Dept. of Entomology, *Raleigh, North Carolina* 27607 (P01 ES 00044-15)

This project has a two-fold component concerning studies directed to biochemical and environmental toxicological research. The biochemical aspects are primarily involved with proteins, specially involved with molecular interactions. Dauterman's project is devoted to a study of pathways of metabolism effected by transferases and includes partial purification of these enzymes. Hodgson's project is an attempt to characterize the several components of P-450 mediated activities, including ligand interaction. Main's effort concerns purification of cholinesterase and kinetic properties of purified enzymes. Moreland's project concerns the effect of herbicides on the sequence of phosphorylative activities in mammals. Guthrie's project is directed to comparative penetration of dermal and oral applications of pesticides and their distribution by blood proteins.

The environmental aspects are divided between studies of the possible genetic effects of a number of xenobiotics and the possible effects on health of agricultural workers who enter fields previously treated with OP insecticides.

ENVIRONMENTAL HEALTH SCIENCES CENTER GRANT

R.R. Suskind, University of Cincinnati, School of Medicine, Dept. of Environmental Health, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221 (P30 ES 00159-14)

Environmental Health Sciences Center Grant at the University of Cincinnati provides core support for interdisciplinary, in-depth research on environmental health problems of public health significance. The objective is to enhance understanding of environmental hazards affecting human health and components of man's ecosystem so that detrimental affects may be prevented and controlled. The scope of the research effort for which Center resources are used covers a wide range of interests: from molecular aspects of biological effects. To the study of populations at risk, as well as identification and quantitation of hazard factors in the environment.

The problem areas for which multilevel approaches are used include: 1) The role of essential trace metals in health and disease as influenced by environmental factors. 2) Health problems of non-essential toxic metals. 3) The behavioral parameters of environmental hazards. 4) The health aspects of energy sources, particularly fossil fuels. 5) The toxicology of plastics and their combustion products. 6) The carcinogenic, mutagenic, and teratogenic aspects of environmental hazards. 7) The toxicologic and health aspects of drinking water contaminants and wastewater factors. 8) Pulmonary metabolism and toxicology of environmental agents. 9) The clinical and epidemiologic study of occupational and community hazards. 10) The identification, measurement and control of environmental contaminants in air, water, wastes, industry, agriculture, consumer products, etc.

TOXICITY OF ORGANIC MERCURY FOR THE FETUS AND NEWBORN

M.D. Maines, University of Illinois, Medical Center at Chicago, School of Basic Medical Sciences, Dept. of Pharmacology, *1853 W. Polk St., Chicago, Illinois* 60680 (R01 ES 00820-07)

Numerous infants born to women consuming foods contaminated with organic mercury during pregnancy have exhibited severe neurologic sequelae after birth. Because of similarity to the human with respect to reproductive parameters, fetal maturation and placental transport, monkeys (Macaca mulatta and M. arctoides) will be used for the following studies. 1) Localization of methylmercury and sites of damage in the macaque brain are being compared in the fetal and adult monkey. 2) The teratogenic potential of methylmercury in the embryonic macaque will be evaluated. 3) Potential therapeutic measures will be examined where a differentiating organism is involved. 4) Women of child-bearing age also exposed to phenylmercury and mercury vapor. Thus, measurements of placental transfer and fetal toxicity following maternal administration of these substances are to be carried out.

ENVIRONMENTAL HEALTH SCIENCES CENTER GRANT

I.J. Selikoff, City University of New York, Mount Sinai School of Medicine, School of Medicine, Dept. of Community Medicine, *5th Ave. at E. 100th St., New York, New York* 10029 (P30 ES 00928-06S1)

The research program will be focused in seven program areas: effects of low-level, long-term exposure to environmental agents, multiple-factor interactions, environmental cancer, asbestos-associated disease, biological properties of inorganic microparticles, halogenated aromatic hydrocarbon and related chemicals and evaluation of disease potential new suspect environmental agents. In this we are primarily concerned with human health effects and utilize population studies as an essential methodolgical approach, with interdigitation of epidemiological, clinical, biological and physical sciences. Because of the recognized need to evaluate the magnitude of the problems studied environmental evaluation is regularly added to provide quantitative information concerning dose-disease response relationships, to facilitate evaluation of proposals for regulations and control, and prevention of disease. Cooperative studies with occupational groups and identified populations in the general community subject to specific exposures, provide an effective approach to such research aims and serve further to build the application of information into the process of seeking the data. Too, such investigations serve to identify groups of people which have been exposed to these agents, i.e., high risk groups. Preventive surveillance becomes feasible, in addition to modification of adverse exposure.

STUDIES IN ENVIRONMENTAL PHARMACOLOGY

A. Kappas, Rockefeller University, Lab. of Metabolism Pharmacology, *66th & York Ave., New York, New York* 10021 (R01 ES 01055-06)

The present proposal is a renewal application for USPHS grant ES-0-1005 which was awarded during 1974-1979. This application extends the work on toxicology in ES-0-1055 by examining in detail using various tissue culture systems, animal models, and man the interacting effects of environmental chemicals, drugs, hormones, nutrition and genes on the biology and function of the heme-cytochrome P-450 systems. We will extend our earlier work on developing micro-assays for enzymes and components of the heme pathway since heme, serving as the prosthetic group of cytochrome P-450, plays a key role in the detoxification (and sometimes activation) of endogenous and exogenous chemicals. Tissue model systems are used extensively to study the biological impacts of environmental chemicals and newly developed techniques which include isolated nervous system cultures, alveolar macrophage cultures, erythroid differentiation (Friend-virus infected cells) and mitogen-stimulated lymphocytes show considerable promise in helping to elucidate the actions of organic pollutants and toxic metals, on cellular differentiation and metabolism. Study of the toxicity of organometals for heme-P-450 systems are newly planned and already reveal major deleterious effects of these substances on heme mediated functions. Biological protective mechanisms against certain toxic metals are examined and studies of the role of nutritional factors in modifying (enhancing/increasing) the biological impacts of chemicals in man are proposed. Humans receive the bulk of their exposure to exogenous chemicals through their diet - and since the proteins, carbohydrates and fats themselves contain chemicals which affect the heme-P-450 systems nutritional/toxicological interactions of clinical importance can be anticipated. Finally, extensive studies of the metabolism of steroid hormones and of the heme-P-450 systems in various worker populations exposed to specific environmental chemicals at work sites are planned in order to determine the nature and extent of derangements of these systems which our preliminary studies (lead, PCB workers) have already shown may characterize such high-risk populations.

2.1093,

NEUROBIOLOGY OF ENVIRONMENTAL POLLUTANTS

M.R. Krigman, University of North Carolina, Chapel Hill Campus, School of Medicine, Dept. of Pathology, *Manning Dr., Chapel Hill, North Carolina* 27514 (P01 ES 01104-05)

The main objective of this Program is to elucidate the effects of environmental pollutants on the development and function of the central nervous system. Basically the Program represents a multidisciplinary approach for studying the sometimes subtle morphological, biochemical and functional (physiological/behavioral) effects of various toxic agents which are of growing concern to our society by bringing to bear variety of existing biomedical techniques. Once such adverse effects have been characterized in well-defined animal models in controlled experimental situations, they can then be specifically searched out in the more complex human clinical population. In addition, the development of new approaches and techniques for discerning adverse effects is a major objective of the Program. By meeting these objectives, a better understanding of animal models, the development of 'evocative' or 'provocative' diagnostic tests, and screening of potential therapeutic agents are expected to be gained and thereby provide a more rational basis for recognizing and dealing with pollutant-induced syndromes.

EFFECTS OF SO2 AND RESPIRABLE PARTICULATES ON HEALTH

B.G. Ferris, Harvard University, Boston Campus, School of Public Health, Dept. of Physiology, *55 Shattuck St., Boston, Massachusetts* 02115 (R01 ES 01108-06)

The objective of this study is to evaluate the effects of low levels of SO2 and respirable particulates on the health of human beings and to identify whether there is a degree of interaction between these pollutants at these levels. Sulfates and sulfites and nitrates and nitrites as well as ozone and nitrogen dioxide will also be monitored. Six communities have been selected that have different levels of SO2 and respirable particulates, two high, two intermediate and two low. Random samples of the adult population (25-74) have been selected and studied by means of a standard respiratory questionnaire and simple tests of pulmonary function. Occupational and residential histories have been obtained as well as smoking habits. A cohort of children from each community has been selected and studied annually. Both of these population groups are being followed prospectively. Historical data on the levels of air pollution helped us to select the communities. We have continued monitoring in each area by means of Central stations where continuous monitors are used and we have established 10 or more satellite stations in each community where we measure 24-hour samples for SO2, NO2 and mass respirable particulates (MRP) both indoors and outdoors. We have done some preliminary studies with personal samplers for MRP. We need to do more of this type of sampling in order to have better estimate of the individual's actual exposure as he moves about during the day. We expect from all this air monitoring to have a better estimate of the exposure of the population rather than use only the data from a Central site. Neutron activation has been used to try to identify the source of the particulates and to determine whether the composition indoors is similar to that out-of-doors or not.

HUMAN RADIOACTIVITY DOSE STUDY

B.S. Pasternack, New York University, School of Medicine, Dept. of Environmental Medicine, *550 1st Ave., New York, New York* 10016 (R01 ES 01120-03)

The aim of our studies is to evaluate the health effects on local or global populations from the nuclear power industry. The nuclides which are under most vigorous attack are the long lived alpha-emitting isotopes of plutonium, americium and curium. Also, the gaseous beta-emitting fission product Kr-85 is entirely released during fuel reprocessing and is globally dispersed. For all nuclides, the most important dose estimates are to cells in bronchial epithelium and cells on bone surfaces.

The long lived alpha emitters will almost certainly be dispersed during fuel reprocessing. However, their effort is local not global and at worst a single community could be affected. The most important pathway for exposure to the actinides is through inhalation following resuspension of contaminated soil particles. Additional exposure is through absorption after material is cleared from the lung and swallowed. However, absorption from the G.I. tract is small (approximately 5 x 10 to the minus 4th power) and the primary dose is to the lung. The cell doses will be estimated for a reference contamination level of soil for each nuclide.

Fortunately, we have a history of exposure to the naturally occurring actinide Th-232 so that we are in a position to predict the behavior of plutonium, americium and curium after inhalation and ingestion. These cell dose estimates from waste dispersal may then be compared in a meaningful way to those which occur naturally from Th-232.

A comparison of these cell dose values with the dose delivered to individuals near to conventional coal- or oil-fired plants is also performed. The data on release of natural activities from these plants are scanty. However, we will attempt to measure at least one contributor to dose Rn-222, to provide some basic data for dose estimation.

TRACE CONTAMINANTS:

T.W. Clarkson, University of Rochester, School of Medicine & Dentistry, Dept. of Radiation Biology & Biophysics, *601 Elmwood Ave., Rochester, New York* 14627 (P30 ES 01247-05)

This grant provides core support for a program on trace contaminants with special emphasis on heavy metals. Several interrelated research programs in environmental toxicology have grown to the point at which consolidation into a center offers clear scientific and administrative advantages. The center will provide core facilities in terms of analytical and histopathological laboratories and services in data processing, pharmacokinetics modeling and biomathematics. It will provide resources to develop embryonic research ideas to the point at which independent support may be obtained. The core faculty will provide long-term continuity of professional expertise and experience in the general field of environmental health science, will provide a national resource to respond to urgent needs in its field, and will provide training for new professionals in the field.

The research in the center will be restricted to those trace contaminants most likely to affect human health. In the immediate future, the center will concentrate on the toxic heavy metals (Cd, Hg and Pb), in continuation of well-established projects at Rochester. Since multiple exposures (e.g., dietary methylmercury and selenium from pelagic fish) also occur, the interaction of heavy metals with other substances will be studied as well.

The center will pursue a coordinated program of studies on exposed human populations, on volunteers, and laboratory animals. This program has drawn support in the past, and will continue to draw support from virtually all the classical disciplines available in the medical center.

HEAVY METALS AS ENVIRONMENTAL HAZARDS TO MAN

T.W. Clarkson, University of Rochester, School of Medicine & Dentistry, Dept. of Radiation Biology & Biophysics, *601 Elmwood Ave., Rochester, New York* 14627 (P01 ES 01248-04)

Quantitative estimates of the human health hazards posed by toxic metals in the environment play the key role in setting realistic exposure standards and in devising efficient preventive measures. Three recognized heavy metals provide the focus for this program project: mercury (both as methylmercury and as metallic mercury vapor), cadmium and lead. Since toxicity is typically both defined and determined by multiple factors, the research plan is also multidimensional. It encompasses investigations of the physical and chemical properties of metals and metal compounds that determine how they enter the body; of how they are handled (distributed, metabolized) by the body and its organ systems; of their capacity to impair the processes of reproduction and development; of their action on behavior and the nervous system; of their potential for tissue pathology; of their impact on the health of selected human populations.

AUDITORY EFFECTS OF LONG EXPOSURE TO LOW LEVELS OF NOISE

J.H. Mills, Medical University of South Carolina, School of Medicine, Dept. of Otolaryngology, *80 Barre St., Charleston, South Carolina* 29401 (R01 ES 01301-05)

The major objective is the specification of the qualitative and quantitative facts of noise-induced hearing loss, particularly asymptotic threshold shifts in human observers. A second objective is to specify the audiometric correlates of asymptotic threshold shifts, particularly temporal integration, psychophysical tuning curves, and physiological response assumed to arise from the brain stem and auditory cortex. Groups of human subjects are exposed to noise for durations as long as 48 hours. Measurements are made before, and after the noise exposure as well as during quiet periods interspersed within an exposure. The exposures are selected in order to evaluate the Equivalent Power Model and/or to noise produce a given temporary hearing loss which can be evaluated with current psychophysical and physiological tests of hearing. Results are expected to have a significant impact on the topic of noise-induced hearing loss and in establishing criteria for the development of the acoustic environment. In addition, many of the methods developed here have immediate application to the diagnosis and treatment of hearing loss and deafness, particularly in infants and young children.

2.1099,

EFFECT OF ATMOSPHERIC POLLUTANTS ON PULMONARY DEFENSES

E. Goldstein, University of California, Davis Campus, School of Medicine, Dept. of Internal Medicine, *Davis, California* 95616 (R01 ES 01327-04)

The proposed research will deal with the role of metallothionein in cadmium metablism as well as toxicity. A radioimmunoassay procedure will be developed to measure metallothionein. Using this procedure, plasma and urine samples from animals experimentally exposed to cadmium and from occupationally exposed humans will be assayed for metallothionein and its level will be correlated with renal tubular dysfunction. The human samples will be made available through collaboration with other investigators.

Genetic predisposition for sensitivity to cadmium-induced testicular damage and hypertension has been suggested. This will be evaluated with respect to metallothionein levels in tissues. Inbred strains of mice will be used to study the relationship of metallothionein and testicular damage. Tissues from rats made hypertensive in response to chronic cadmium feeding will be obtained through a collaborative arrangement with another laboratory.

2.1100,

EPIDEMIOLOGIC STUDY OF CORD IN COHORTS

R. Detels, University of California, Los Angeles Campus, School of Public Health, Dept. of Epidemiology, *405 Hilgard Ave., Los Angeles, California* 90024 (R01 ES 01473-04)

This is a proposal to complete retesting of lung function in two of four demographically matched cohorts and to complete analysis of results in all four cohorts. The 15,164 cohort members live in four areas of Los Angeles which have been historically and concurrently exposed to 1) moderate levels of photochemical oxidants, 2) high levels of secondary pollutants including photochemical oxidants, 3) SO2/particulates, and 4) minimal levels of pollutants. Pollutant levels are continuously measured by monitoring stations of the Southern California Air Quality Management District located within or adjacent to the study areas. Lung function tests administered at the mobile laboratory include spirometry, single breath nitrogen washout curve and plethysmography. Tests are readministered to a 4% sample at the UCLA Pulmonary Function Laboratory to determine reliability and identify fixed errors which may arise at the mobile laboratory.

Baseline testing in all four areas and retesting in two areas will have been completed by 1980. Results of baseline testing were worse in the three areas exposed to pollutants. The two cohorts still to be retested were those with the poorest lung function results at baseline and which have been exposed to pollutant mixes distinctly different from the first two areas retested.

The major objectives are to determine 1) if long-term exposure to photochemical oxidants and other pollutants is associated with the initiation and/or promotion of respiratory impairment and/or chronic respiratory disease, 2) which of the lung function tests administered (questionnaire, spirometry-air and He/O2, single breath nitrogen washout curve and body plethysmography) are specific and/or sensitive early indicators of impaired lung function and which are most suitable for use in field surveys.

INHALED AEROSOLS - BEHAVIOR, EFFECTS, AND CLEARANCE

R. Frank, University of Washington, School of Public Health & Community Medicine, Dept. of Environmental Health, *4000 15th Ave. N.E., Seattle, Washington* 98105 (P01 ES 01478-03)

Studies are underway to determine the degree to which hygroscopic growth of particles as they are inhaled affects their deposition in the respiratory system. This is being studied several ways -- through the use of models, animals and human subjects. This approach is expected to provide data which are realistic in the sense of applicability to human studies. The model and animals studies will provide regional scale detail of particle deposition.

We are also measuring the extent of neutralization of inhaled acid sulfate aerosols by respiratory NH3 prior to deposition. The production of NH3 in the mouth is being related to specific bacterial organisms. The final part of this objective is to identify populations which, because of low levels of NH3 in the upper airways, may be at increased risk if exposed to acid sulfates.

The third objective is the study of the functional responses of allergic adolescents to acid aerosols present in community air. The response to these aerosols is being studied both at rest and during exercise.

2.1102,

RESPIRATORY ANAPHYLAXIS TO INDUSTRIAL CHEMICALS

M.H. Karol, University of Pittsburgh, Graduate School of Public Health, Dept. of Industrial Environmental Health Sciences, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (R01 ES 01532-03)

An animal model of respiratory hypersensitivity to industrial chemicals has been developed using guinea pigs. Repeated exposure of animals to antigen aerosols, containing hapten-protein conjugates, results in pulmonary sensitization and antibody production to the haptenic portion of the antigens. Using this procedure, sensitivity to both aliphatic and aromatic chemicals has been achieved.

Proposed research will be directed toward inducing pulmonary sensitization in guinea pigs by repeated exposure to vapors of industrial chemicals, i.e., the haptens alone. Sensitization will be assessed by: increased respiratory rate, bronchial constriction, specific antibody formation. If successful, chemicals known to have allergenic abilities in man will be used for animal sensitization. In this way the allergenic potencies of various industrial chemicals can be evaluated in the guinea pig and compared to their reported potencies in man. Such comparisons will enable assessment of the value of the guinea pig as an animal model for pulmonary sensitization of man.

Research will also focus on use of hapten-protein conjugates to detect hapten-specific IgE antibodies in sensitized industrial workers. To date, antigens formed by reaction of p-tolyl isocyanate with human serum albumin have been very effective in detecting antibodies to TDI. Evaluation of sera from additional

workers will indicate the potential applicability of such serologic tests for pre-employment screening of industrial workers.

BIBLIOGRAPHIC REFERENCES: Karol, M.H., Ioset, H.H. and Alarie, Y.C. 1978. Tolyl-specific IgE antibodies in workers with hypersensitivity to toluene diisocyanate. Am. Ind. Hyg. Assoc. J. 39: 454-458. Karol, M.J., Ioset, H.H., Riley, E.J. and Alarie, Y.C. 1978. Hapten-specific respiratory hypersensitivity in guinea pigs. Am. Ind. Hyg. Assoc. J. 39: 546-556.

BEHAVIORAL EFFECTS OF LEAD EXPOSURE IN CHILDREN

P.B. Hammond, University of Cincinnati, School of Medicine, Dept. of Environmental Health, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221 (P01 ES 01566-01A1)

This is a prospective study of the effects of lead exposure on the physical and mental health of children. It is composed of both human and animal studies. The study of children is to be conducted in the natural environmental setting where elevated lead exposure is common. We hope to establish whether and under what environmental circumstances lead causes adverse health effects. Prospective mothers will be recruited into the study during the first or second trimester of pregnancy. Their offspring will be followed for five years. Since many factors are known to influence the behavioral and intellectual development of a child, a multivariate design will be used rather than design which employs a control versus experimental group comparison. Data to be collected on each child include; prenatal and delivery records; physical growth, behavioral and intellectual profiles beginning at 3 days of age and repeated at 9 month intervals; blood lead, FEP, and iron status at 3 month intervals; evaluation of the home environment with respect to quality of child care and sources of lead exposure. The animal studies will use rats exposed perinatally to low levels of lead. Tissue and blood will be monitored for lead and trace metal content. Other measures will include neurotransmitter metabolism, electrophysiological assessment and behavioral evaluation. The animal studies will explore critical periods, persistence and reversibility of toxicity and the utility of hematopoietic indices for identifying individuals at risk for subsequent behavioral impairment. Both human and animal studies will examine the role of age, duration and levels of lead exposure as determinants of effect as well as exploring leads interaction with numerous environmental variables as a determinant of toxicity. The ultimate purpose of all research on neurobehavioral effects of lead is to establish the minimal level of exposure at which effects may occur, as reflected in biological indices e.g. blood lead. A prospective study of the type proposed is necessary to answer crucial questions pertaining to the maximal safe level of exposure at any time in the child's life. Only with such a study can regulatory agencies institute proper control of exposure.

LONGITUDINAL STUDY OF AIR POLLUTION ON MORTALITY

S.J. Finch, State University of New York, Stony Brook Campus, School of Engineering & Applied Science, Dept. of Applied Mathematics & Statistics, *Stony Brook, New York* 11794 (R23 ES 01686-02)

This study examines whether reductions in air pollution are associated with reductions in the prevailing mortality rates. The areas considered are census tracts that have 'high' residential stability; this restriction reduces the effect of migration into and out of the area. Analysis of data from Buffalo will be completed by the end of the first year of the project. Next year, data from Detroit, Seattle, and the major cities of Ohio will be analyzed. Results to date from Buffalo support the hypothesis of an association between reduced air pollution levels and a reduction in the prevailing mortality rate; however, these results are not statistically significant. Consideration of the larger data sets will clarify this point. In addition to time trend analyses, the study is examining whether there are any unusual geographical clusterings of mortality rate changes and performing other exploratory analyses. The deaths are analyzed by cause of death to specify the nature of the putative air pollution and mortality association. Primary attention, of course, is given to lung and chronic heart disease.

CARCINOGENIC IMPACT OF RADON IN WATER SUPPLIES

H.M. Prichard, University of Texas, Health Science Center at Houston, School of Public Health, Dept. of Environmental Science, *6515 Freeman, Houston, Texas* 77025 (R23 ES 01742-03)

The goal of this project is to evaluate the feasibility of an eventual epidemiological test of the linear, non-threshold model of radiation carcinogenesis using health effects data from communities with populations exposed to varying levels of Radon-222 in the water supplies. To accomplish this goal, two subprojects must be carried out concurrently: 1. The establishment of a data base consisting of radon levels in selected community water supplies; 2. The development of an algorithm which produces a reasonable estimate of the community population dose increment as a function of practical variables such as radon content of the water supply, meteorological data, and local demographic and architectural factors.

Data for the first sub-project is being collected by a large-scale systematic sampling program which makes use of mail-out sampling kits and a simplified analysis technique developed in this Department. It is projected that by the end of the project, the water supplies of communities containing up to 15 million inhabitants can be characterized.

Laboratory and field experiments are being conducted to determine radon levels, radon progeny equilibrium status, unattached fraction, and other dose modifying factors in the indoor enivronment. Other experiments seek to document the relationship of indoor radon levels to water consumption and radon content of the water.

CHILDHOOD LEAD, PYRIMIDINES AND METABOLIC DEBRIS

C.R. Angle, University of Nebraska, Medical Center, School of Medicine, Dept. of Pediatrics, *42nd & Dewey Aves., Omaha, Nebraska* 68105 (R01 ES 01857-02)

Our current studies in children and in the rat confirm observations on lead workers that the red cell of both man and the rat contains a monophosphoesterase specific for pyrimidines, pyrimidine 5' nucleotidase (E.C. 3.1.3.4, P5N) that dephosphorylates cytidine monophosphate (CMP) and uridine monophosphate (UMP). P5N is inhibited at low levels of blood lead with a negative linear correlation of blood lead and P5N. Pyrimidine phosphates (CMP, CDP, CTP, UMP, UDP and UTP) are present at very low levels in the red cell but accumulate with depression of P5N. Studies of the red cell nucleotide profile of lead exposed children and adults are underway. A primary deficiency of P5N as well as a high blood lead results in a basophilic stippling of the red cells, representing incompletely degraded RNA. We are investigating the hypothesis that an increased blood lead results in basophilic stippling by the feedback inhibition of ribonuclease and phosphodiesterase by the accumulation of pyrimidine nucleotides as well as by direct enzymatic inhibition by lead.

ABESTOS AND CANCER

M.L. Warnock, University of California, San Francisco Campus, School of Medicine, Dept. of Pathology, *551 Parnassus Ave., San Francisco, California* 94122 (R01 ES 02117-02)

Our previous studies have failed to demonstrate a relation between numbers of pulmonary asbestos bodies and the presence of carcinoma of the lung or gastrointestinal tract in workers with very low asbestos exposure. Asbestos bodies, however, represent only a part, and perhaps only a small part, of the total lung asbestos burden, which is composed of coated bodies as well as uncoated fibers. It is possible that a relation exists between numbers of uncoated asbestos fibers and the presence of bronchogenic carcinoma. This study will attempt to quantify and type the uncoated asbestos fibers as well as asbestos bodies at various sites in the lung. A new preparative method has already been developed and used for examining and identifying the nature of the cores of asbestos bodies by electron diffraction. The same method will be used to identify further these same bodies by electron microprobe analysis. An additional preparative method has been devised for recovering uncoated asbestos fibers. Relations between numbers of coated and uncoated asbestos fibers, as well as their relative locations within the lung, will be tabulated, and an attempt will be made to correlate numbers of types of fibers with the presence or absence of carcinomas. We have previously shown that numbers of asbestos bodies are related to occupation; an attempt will be made to establish whether a similar situation exists for uncoated fibers or whether they are derived from the environment.

DRINKING WATER QUALITY AND COLON CANCER

C.M. Shy, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Epidemiology, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514 (R01 ES 02232-01)

The proposed study will investigate the relationship of drinking water quality to cancer of the colon in North Carolina using the case-control approach. A matched series of living colon cancer cases and hospital controls will be compared with regard to differences in quality of their drinking water and other environmental factors. A substudy will determine whether past diet is a confounding factor. Sample size and methodology have been chosen so as to detect small differences in risk, and water quality indices have been constructed for periods 20 and 30 years in the past to account for the issue of latency. These indices, which are based on source, treatment and prior use characteristics, provide a basis for establishing a gradient of carcinogenic exposure. With this information, estimates of risk for each exposure level will be obtained and comparisons between these will be made. Using this rigorous approach, it will be possible to provide meaningful data on the importance of water-borne carcinogens in the etiology of a leading cancer site.

SEQUELAE TO CHILDHOOD LEAD EXPOSURE - A TWIN STUDY

M. Marmor, Cornell University, Ithaca Campus, New York State College of Veterinary Medicine, Dept. of Preventive Medicine, *825 Veterinary Research Tower, Ithaca, New York* 14853 (R01 ES 02267-02)

The purposes of this research are to determine if there are long-term consequences of increased lead absorption in children and to evaluate the current criteria for treatment of lead overexposed children. Existing studies of neuropsychologic sequelae to low-level lead overexposures have yielded inconsistent results. The present research will utilize a twin methodology to control for exposures to environmental risk factors other than lead and to control for genetic and cultural factors which might otherwise lead to confounding in outcome measures such as intelligence quotients. Members of twin pairs with a historyof increased lead absorption will be compared with less-exposed twin siblings on a number of neuropsychological measures and school performance. The population of twins will be obtained from the records of the New York City Bureau of Lead Poisoning Control. Premorbid conditions will be determined from birth records, hospital/doctors records, and from parental interviews.

EPIDEMIOLOGICAL RISK MODELING AND ESTIMATION

H.D. Tolley, Battelle Memorial Inst., Pacific Northwest Laboratories, *P.O. Box 999, Richland, Washington* 99352 (R23 ES 02493-01)

The research project proposes to implement and investigate stochastic compartment model methodology as a tool in modeling and estimating epidemiological risk due to environmental stresses. Although not all modeling of risk factors can be accomplished using a compartment model formulation, most epidemiological models of assessing risk currently in use can be quite simply put into this framework. In this setting, both an empirical and a theoretical investigation will be made of the current methods of risk estimation including bias, robustness and statistical power of the tests. Which kinds of hypotheses can and cannot be examined using the various methods will particularly be studied.

The model proposed is easily generalized to represent more complex survival-death processes. This generalization lends itself to the estimation of risk when more specific mechanisms regarding possible environmental hypotheses are proposed. Once such example is the estimation of latency in cancer studies. A second example is in extending the definition of risk to multiple cause mortality data incorporating intermediate as well as underlying causes of death in assessing disease linkage (correlations and causal sequencing). Thus, the second aim is to develop a methodology which will expand the family of risk estimable models from epidemiological data. As in all compartment formulations, however, problems of parameter identifiability are present. Which parameters of these more complex models can be practically identified and the robustness of these estimates under model fluctuations is also to be examined.

THE ROCHESTER, MINNESOTA EPIDEMIOLOGY PROGRAM PROJECT

L.T. Kurland, University of Minnesota, Mayo Graduate School of Medicine, School of Medicine, Dept. of Epidemiology & Med Statistics, *200 1st St. S.W., Rochester, Minnesota* 55901 (P01 GM 14231-13)

The central data bank of the Rochester Program Project (RPP) consists of a file of medical diagnoses and surgical procedures covering the population of Rochester and Olmsted Counties, MN, for a period of more than 40 years. These data have been assembled from records at Mayo Clinic and other medical care centers and are considered a national resource for epidemiological studies. The medical records upon which this resource depends cover essentially all local physician-patient contacts and include records for home, outpatient and hospital visits, and autopsy data. This resource is maintained at the Mayo Clinic, but is available to visiting scientists, students from other universities, and health agencies.

More than 115 epidemiological studies using this data bank have been completed. These include studies of incidence and outcome as well as case-control comparisons and prospective studies. Underway at the present time are several descriptive epidemiologic studies on diabetes, stroke, ischemic heart disease, head trauma, rheumatoid arthritis, fractures of the extremities, pituitary adenomas and various malignant neoplasms; case-control studies have been developed on leukemia, ovarian cancer and breast cancer; prospective-type studies are underway on the long-term effects of Flagyl and DES; and cost-effectiveness studies have been developed on the CAT (brain) scan and the total body scanner, and manpower needs are being measured for the surgical subspecialties.

The BCFF is to be discontinued unless support is forthcoming from another source. In that event, the program will be extended to study many other topics, such as mental retardation, childhood schizophrenia, and other psychiatric and behavioral problems.

SUPPORT FOR STUDY OF INHERITED DISEASES

A.G. Motulsky, University of Washington, School of Medicine, Dept. of Medicine/Genetics, *A-300 Health Sciences Ctr., SC-64, Seattle, Washington* 98195 (P50 GM 15253-13)

This application relates to an interdisciplinary center in medical genetics and inherited diseases. The principal objective is to obtain more fundamental understanding of gene action in man at the level of molecules, cells, individuals and population, and to elucidate the role of genes in the causation of human disease. The Center aims to apply new knowledge to disease prevention and management. Areas to be investigated include: a) biochemical human genetics (proteins and enzymes of formed elements of blood and serum, hemoglobins, pharmacogenetics, developmental genetics); b) genetics of common disorders (coronary atherosclerosis, hypertension); c) genetics of tumor origin; d) somatic cell genetics (X-inactivation, hybridization, complementation, cell cycle mutants); e) cytogenetics (including gametic and early embryonal cytogenetics); f) clinical genetics; and g) statistical genetics.

ANESTHESIOLOGY CENTER FOR RESEARCH AND TEACHING

R.J. Kitz, Harvard University, Boston Campus, School of Medicine, Dept. of Anesthesia, *25 Shattuck St., Boston, Massachusetts* 02115 (P50 GM 15904-12)

The object is to strengthen and continue the development of the Harvard Anesthesia Center established by grant from the National Institute of General Medical Sciences. This research is based in the facilities of Harvard University and its associated teaching hospitals. Our primary aim is to conduct research oriented either directly or ultimately toward improved scientific patient care in anesthesia and toward making such care available to all patients. We conduct a multidisciplinary collaborative research program involving scholars from 16 disciplines and 10 departments in the several faculties of Harvard University. This effort emphasizes studies of relevance to anesthesia and the basic sciences which are its foundation and attempts to make the fullest use of interdisciplinary co peration and advanced technology.

GENETIC ANALYSIS OF MULTIFACTORIAL TRAITS

R.C. Elston, University of North Carolina, Chapel Hill Campus, School of Public Health, Dept. of Biostatistics, *Rosenau Hall, 201H, Chapel Hill, North Carolina* 27514 (R01 GM 16697-11)

Human variability in selected large pedigrees will be studied and analyzed with a view to determining how much of it is due to genetic influences, and where possible the mode of genetic action determined. New statistical techniques will be devised for this purpose, allowing for both qualitative and quantiative multifactorial traits, multiple-generation data. Appropriate computer programs will be written, and applied both to data that have already been collected and to data that will be collected with the special purpose of identifying major genes for such traits. The possible existence of such major genes will be demonstrated by segregation analysis and by searching for linkage relationships between such genes and marker genes in blood. This will lead to a more complete understanding of the determinants involved in such diseases as hyperlipidemia, hypertension and cancer.

PROGRAM PROJECT IN CLINICAL GENETICS

J.M. Opitz, University of Wisconsin, Madison Campus, Medical School, Dept. of Medical Genetics, *307 N. Charles St., Madison, Wisconsin* 53706 (P01 HD 12994-06)

Work in the Wisconsin Clinical Genetics Center (WCGC) includes: 1) Delineation of new birth defect syndromes, their cause, natural history, prognosis and treatment; 2) study of 'known' birth defects to better delineate their phenotypic spectrum, pathogenesis and cause, and the means to detect carriers, and to detect affected individuals prenatally; 3) cytogenetic studies of new and known aneuploidy syndromes; 4) studies of genetic pleiotropy in man; 5) investigations of the nature of gene expression in tissues, organs and cells of individuals (expressivity), in individuals vis-a-vis their genotype (penetrance), and in generations vs. their genotypes (phenotrance), in skeletal dysplasias (achondroplasia, hypochondroplasia), malformation syndromes (Wiedemann-Beckwith syndrome, prune belly syndrome, etc.), and cancers (retinoblastoma, Wilms' tumor, carotid body tumors, multiple glomus tumors and multiple cutaneous leiomyomata; 6) studies of methods of numerical taxonomy in clinical studies and genetic nosology; 7) studies of prenatal diagnosis, the incidence of Down's syndrome and neural tube defects in Wisconsin; 8) studies of the prevalence of developmental disabilities in Burnett Co. and Dane Co. Wis.; 9) health and genealogical surveys of all of the Old Order Amish in Wis., Illinois, Iowa, Missouri and Minnesota; 10) total dissections of fetuses and infants with known (genetic) syndromes and experimental studies of pathogenesis of congenital malformations in aneuploid mice; 11) causal, nosological and empiric recurrence risk studies in severe MR - especially that associated with primary CNS malformations; 12) mutational and genetic analysis of the experimentally (EMS) induced phenomenon of unstable premutation in Drosophila; '3) interdisciplinary studies of phenotype, pathogenesis, cause, nosology and recurrence risk in skeletal dysplasias and human intersexuality; 14) studies of the effects on offspring of parental consanguinity in Wis. rural Catholics; 15) studies on the pathology, anatomy and genetic defects of aborted fetuses and stillborn infants; 16) studies of mucopolysaccharide metabolism and of lysosomal hydrolases in human mucopolysaccharidoses, mucolipidoses, and lipidoses; 17) biochemical, EM, and histochemical studies of many pigment mutations in mouse, mink, and man.

GONOSOMAL ANEUPLOIDY IN CITY HOSPTIAL POPULATIONS

P.V. Tishler, Harvard University, Boston Campus, Peter Bent Brigham Hospital, *721 Huntington Ave., Boston, Massachusetts* 02115 (R01 GM 26373-03)

Screening methods for the rapid determination of Y chromosomal ploidy (peripheral blood leukocyte fluorescence analysis) are being applied to male participants in the national Health and Nutrition Examination Survey (HANES). Analyses are thus far completed on 4642 males in this population, with the finding of five individuals who may have a 47, XYY chromosome constitution. Further studies by different cytologic methods are being applied to these five suspect slides in order to ascertain those with a high degree of probability for the YY karyotype. The physical and psychosocial characteristics of individuals with the YY karyotype will be studied, by means of the other data accumulated on these subjects by the HANES. The present study will thus both determine the prevalence of YY aneuploidy in a general, ambulatory population of adult males and point out any medical or other concomitants that may be causally related to this karyotype.

A further 2000 individuals will be screened for Y chromosomal ploidy in the coming year.

ACUTE AND LONG-TERM CLINICAL TOXICITY OF DRUGS

H. Jick, Boston University, School of Medicine, Dept. of Medicine, *80 E. Concord St., Boston, Massachusetts* 02215 (R01 GM 23430-03)

The proposed research will utilize clinical data to quantitate the acute and long-term toxicity of all drugs commonly used in medicine. The procedures for data collection have been used and found to be effective for ten years. Monitors stationed on hospital wards collect information in a standardized fashion on patient characteristics, drug exposures, the development of clinical complications and final diagnoses. These data are computerized and retrievable in different formats. For patients with medical illnesses, data on 50,000 hospitalized patients are already on hand and available for analysis. Additional data on patients with surgical illnesses are being collected utilizing a system of data collection similar to that used for medical patients. The data allow for the quantitation of the relationships of outpatient drug use to diseases such as cancer, coronary heart disease, renal failure and bone marrow depression. In addition, rates of acute toxicity together with details of type, severity and populations at greatest risk for all commonly used drugs can be estimated. The ultimate goal is to provide practicing physicians with reasonably precise quantitative data on the toxicity of all commonly used drugs so that they may practice therapeutics on a more rational basis.

STATISTICAL METHODS FOR CASE-CONTROL STUDIES

R.L. Prentice, Fred Hutchinson Cancer Research Center, *1124 Columbia St., Seattle, Washington* 98104 (R01 GM 24472-03)

The aim of this continuing project is the development and evaluation of improved statistical methods for the analysis of case-control data. The case-control study is a primary tool for epidemiological research into the relationship between 'exposure' variables or other risk factors and disease incidence. The methods under development promise more precise and comprehensive evaluation of the effect of such exposure variables and may lead to liberalization of case-control study design.

The main focus of this project is the adaptation of prospective disease incidence models to case-control sampling. Models considered include the proportional hazards regression model, in which exposure and other factors are presumed to affect the (instantaneous) disease incidence rate in multiplicative manner, and the associated logistic regression model in which such factors affect the odds-ratio multiplicatively.

We have developed a conditional likelihood procedure for adapting the proportional hazards model to 'time-stratified' case-control data. Numerical aspects and estimation properties based on this likelihood will be studied under this proposal. A central aim of the proposal is the adaptation of the same model in a form that utilizes the whole time-exposure history of individual study subjects and need not require time-stratified sampling. In addition we expect to complete, under this proposal, ongoing work showing the duality of representation and estimation from prospective and retrospective logistic models. Some non-iterative methods for logistic estimation will also be further studied.

INTENSIVE DRUG SURVEILLANCE IN HOSPITALIZED CHILDREN

A.A. Mitchell, Childrens Hospital Medical Center, Dept. of Medicine, *300 Longwood Ave., Boston, Massachusetts* 02115 (R01 GM 24781-03)

The Pediatric Drug Surveillance ('PeDS') Program is an epidemiologic study of the clinical effects of drugs in hospitalized children. The objectives of this research project are to study the acute and long-term clinical effects of drugs in the pediatric population; in particular, we intend to identify previously unsuspected acute effects of drugs and previously unsuspected relationships between specific diseases and drugs used on an out-patient basis. In addition, the project seeks to evaluate patient factors that may influence the outcome of drug therapy. Given the relative lack of information about drug effects in the newborn, this project intends to study the effects of

drugs in the newborn with particular emphasis. This project also seeks to address certain methodologic issues related to intensive drug surveillance; for example, we intend to evaluate both the feasibility and utility of conducting drug surveillance in community hospitals. Finally, to increase the efficiency of in-hospital intensive drug surveillance, the project will develop methods that utilize existing hospital computer files to obtain information currently obtained through other means.

PATH ANALYSIS OF FAMILY RESEMBLANCE

D.C. Rao, University of Hawaii System, Manoa Campus, Population Genetics Lab., *Bachman Hall, Honolulu, Hawaii* 96822 (R01 GM 24941-02)

The proposed research develops appropriate methods for path analysis of quantitative traits in nuclear families, incorporating specific maternal effects with extensions to cover pedigree structures. This would enable tests for maternal effects, assortative mating and basic hypotheses on genetic and environmental effects. These methods will be applied to lipoprotein concentrations, IgE levels and periodontal disease and blood pressure. We also propose to develop a separate theory of path analysis for prevalence data on semi-continuous traits with applications to schizophrenia, cleft lip and palate; this will be developed through conditional probabilities and polychoric functions.

ANTECEDENTS AND CONSEQUENCES OF CHILD BURN INJURIES

M.S. Knudson, University of Texas, Medical Branch at Galveston, School of Medicine, Dept. of Psychiatry & Behavioral Sciences, *300 University Blvd., Galveston, Texas* 77550 (R01 GM 25016-02)

The purpose of this study is to analyze pre-existing data on psychosocial background characteristics of a population of 330 severely burned children and to assess the feasibility for a longitudinal, prospective study of the adjustment of severly burned children and their families. Specifically, this study will develop a profile of the burned child and his/her family in terms of age, sex, socioeconomic status, family stability, family stress and the child's pre-burn characteristics. These background variables will in turn be related to the child's role in the burn accident and the severity of the burn injury. A pilot follow-up of 50 of the subjects will be carried out in order to assess the feasibility of a long-term follow-up study. In addition to the analysis of existing data, this project will develop a research design and data collection package for a 3-year prospective study, which will include specific hypotheses relating background characteristics and the severity of the burn to long-term adjustment and a control population of unburned children.

EPIDEMIC PROCESSES, ESTIMATION AND SEQUENTIAL ANALYSIS

L. Billard, State University System of Florida, Florida State University, School of Arts & Sciences, Dept. of Statistics, *205 Wildwood Dr., Tallahassee, Florida* 32306 (R01 GM 26651-01)

This proposal addresses itself to three distinct areas of research: (1) modelling as it pertains to epidemic processes; (2) estimation within the content of analysing epidemic data, as well as estimation of Markov chains in general; and (3) sequential analysis with emphasis on the development of optimum tests for two-sided alternative hypotheses. While the immediate concern in (1) is with epidemic models, the mathematics to be developed will also be widely applicable to many other stochastic processes. The work on estimation procedures will be concerned largely with maximum likelihood, empirical Bayes and time series methods. The applicability of this work will venture well beyond the area of epidemics which originally motivated the research. Finally, the sequential tests to be developed will attempt to combine the essential features of Wald's sequential probability ratio tests and diffusion processes.

OCULOCUTANEOUS PIGMENT DEFECTS

C.J. Witkop, University of Minnesota, Minneapolis Campus, School of Dentistry, Dept. of Human & Oral Genetics, *6 Morrill Hall, Minneapolis, Minnesota* 55455 (R01 GM 24558-08)

Ocular and oculocutaneous pigment defects in man and animal homologues are investigated for their clinical, ophthalmologic, biochemical, ultrastructural, genetic, epidemiologic and pleiotropic features to determine the biochemical or morphologic basis of these defects with the final objective of seeking therapeutic or other means of ameliorating, treating or preventing these disorders. Among the pleiotropic effects common to the oculocutaneous disorders to be studied are the abnormal routings of the optic and possibly optic neuronal tracts that are associated with a lack of pigment in fundus and inner ear respectively. Mechanisms which may be defective in some forms of albinism will be investigated by testing the cells for B adrenergic and hormone receptor sites, the influence of calcium flux on tyrosinase and melanin, and the protein and lipid content of melanosomes in pigmented and various mutant strains of mice. Studies to identify the abnormal inclusions in YM and HPS cells are presented. Linkage studies for YM, HPS, and various African albino types will be done to determine genetic homology. The pathogenesis of skin cancer and the corresponding development of chromosomal abnormalities will be studied in Africa. Heterozygote detection tests will be developed.

MULTIPLE SCLEROSIS, PARKINSONS, AND OTHER MULTIFACTORIAL NEUROLOGICAL DISORDERS (ABBREV)

R. Eldridge, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Neurogenetics Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02167-04 ID)

In this project we are coupling genetic study of selected families and twin pairs, epidemiologic, immunologic, serologic and neurochemical studies. Disorders due to multiple factors include multiple sclerosis and Parkinsonism. This approach should clarify the etiology of these diseases, indicate individuals or populations at high risk and suggest mechanisms of prevention and treatment.

To date, 14 presumptive 'Multiple Sclerosis' families have been studied and 93 twin pairs with this condition have been ascertained and partially evaluated. A total of 48 Twin pairs with Parkinsonism have been ascertained and multidisciplinary evaluation instituted.

CONFERENCE ON NEUROLOGICAL EPIDEMIOLOGY

B.S. Schoenberg, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Epidemiology Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02307-02 OBE)

An international two-day conference on neurological epidemiology was held in Washington, D.C., on May 15-17, 1977. Approximately 50 representatives from Asia, Africa, Europe, Latin America, and the U.S. attended. The various speakers and discussants discussed current knowledge in neuroepidemiology and stressed the applicability of this information to the practice of neurology and neurosurgery. A national one-day course on the principles of neurological epidemiology was offered. The papers and discussions for this conference have been edited and will be published in the near future.

EPIDEMIOLOGY OF PROLAPSED LUMBAR AND CERVICAL DISCS

J.L. Kelsey, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (R01 NS 15230-02)

This is a case-control study of the epidemiology of prolapsed lumbar intervertebral disc and prolapsed cervical intervertebral disc. Demographic characteristics and exposure to possible risk factors in surgical, probable, and possible cases of each of these conditions in the age range 20-64 years will be compared to demographic characteristics and exposure to possible risk factors in two control groups in the same age range. All cases and controls are people who have sought medical care at hospitals and at physicians' offices. One control group is composed of people without known spinal disorders and the second comprises people with back and neck problems other than prolapsed discs. Persons with previous prolapsed discs or other previous significant back or neck problems are excluded from the case and control groups. Information on demographic variables and exposure to possible risk factors is obtained by means of a structured questionnaire administered by trained interviewers. The possible risk factors of particular interest are driving motor vehicles and using other modes of transportation, occupational characteristics such as prolonged sitting and frequent twisting motions, pregnancies, participation in certain sports, respiratory symptoms, height, and weight. Data collection for this study is now taking place.

AMINOGLYCOSIDE OTOTOXICITY DETERMINANTS

W.E. Fee, Stanford University, School of Medicine, Dept. of Surgery, *Stanford, California* 94305 (R01 NS 14596-02)

Considering that one million patients per year are at risk, human aminoglycoside ototoxicity is not as well understood as it ought to be. This project seeks to develop rapid screening criteria to predict and prevent ototoxicity. In addition, it will determine how radioenzymatic serum aminoglycoside levels best correlate with development of toxicity, what clinical factors predispose to ototoxicity, to determine the incidence of ototoxicity in the various clinical infectious situations reflecting the use of this drug group, and to identify comparable patient groups by computer analysis in an effort to make comparative evaluation of the toxicities of the different aminoglycosides under similar clinical conditions.

Human subjects will undergo a detailed history and prospective determination of vestibular and cochlear function by electronystagmography and audiometry respectively. Renal function will be assessed utilizing creatinine clearances and serum BUN. Follow-up evaluation will be performmd in three months to determine development of delayed ototoxicity or recovery from ototoxicity.

Data analysis will be performed via the Stanford Center for Information Processing IBM 370/168 computer utilizing program language SPSS, version 7.0.

PERIPHERAL NEUROPATHY CLINICAL RESEARCH CENTER SUPPORT

P.J. Dyck, Mayo Foundation, *200 1st St. S.W., Rochester, Minnesota* 55901 (P01 NS 14304-03)

Controlled clinical trials to test the efficacy of hyperglycemia control in diabetes mellitus, of prednisone versus prednisone and azathioprine in chronic inflammatory demyelinating neuropathies, and of various cytotoxic agents in dysproteinemic neuropathy will be continued. Extensive morphometric, pathologic and lipid compositional studies are being conducted on postmortem and biopsied sural nerve tissue in human diabetic and inherited neuropathies. Studies attempting to induce neuropathy by modification of membrane lipids, studies of structure, turnover, and function of membrane phospholipids and nuclear magnetic resonance studies are being continued as outlined in the grant application. Studies of the role of endoneurial fluid pressure, blood nerve barrier, and role of these in neuropathy production are being pursued. The cellular and molecular mechanisms of lead neuropathy production is being pursued by study of endoneurial lead content related to pathologic abnormality and to rate of cell division after crush. The natural history, pathologic and lipid biochemical abnormalities of a new syndrome with arachidonate deficiency is being investigated. Seroepidemiologic studies of possible viral induced neuropathies are being pursued. Neurophysiologic and pathologic studies of several models of experimental autonomic neuropathy to bowel and bladder will be completed. The prototypes of systems to evalute human joint position and motion and just-subnoxious heat will be developed.

DETECTION OF TIA IN AN ELDERLY COMMUNITY

A. Heyman, Duke University, School of Medicine, Dept. of Medicine, *Box 3711, Durham, North Carolina* 27710 (R01 NS 13643-04)

The purpose of the present study is to carry out a three year surveillance of the morbidity and mortality from cerebrovascular disease among the residents of the Leisure World retirement community in Laguna Hills, California. The information obtained from this survey will be related to data on precursors of stroke available from questionnaires completed in 1976 by

approximately 11,000 persons or 65% of this population. Analyses of these two data files should provide valuable insights into the natural history of transient cerebral ischemic disease (TIA) as well as other risk factors of stroke. Useful information will also be obtained from this survey in regard to the value of such community-wide screening programs for the prevention of stroke.

ETIOLOGY AND PATHOGENESIS OF MULTIPLE SCLEROSIS

D.H. Silberberg, University of Pennsylvania, School of Medicine, Dept. of Neurology, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (P50 NS 11037-07)

We will attempt to establish the Etiology and pathogenesis of multiple sclerosis using several interdependent approaches. This ojective is divided into four areas: 1) the isolation of mammalian oligodendrocytes; 2) analysis of glial cell plasma membranes; 3) virus infection and demyelinating diseases; and 4) immunologic mechanisms of demyelinative CNS disease.

We will use immunologic techniques in an effort to determine the target antigen(s) in oligodendrocyte membrane which interacts with serum from patients with MS. We will characterize other circulating immunologic factors, including antibodies to lipid haptens and alterations in circulating immunocompetent cells. We will carry out similar studies in cells derived from cerebrospinal fluid of patients with MS as one approach to studies of the compartmentalization of the immune response in patients with MS. We will study the biosynthetc processes occurring in isolated oligodendrocytes and in glial cells and the factors which influence those processes.

We will attempt to repeat the successful induction of CNS disease in subhuman primates inoculated with material from patients with CNS disease and study viruses isolated from these primates. We will study the mechanisms of resistance and susceptibility to latent virus infections in the CNS. Mechanisms of humoral and cell-mediated immunological reactions in patients and in animal models will continue to be explored. Viruses isolated in the course of these experiments will be characterized by immunological and biochemical techniques.

2.1193,

ETIOLOGY AND PATHOGENESIS OF MULTIPLE SCLEROSIS

H. Koprowski, Wistar Inst. of Anatomy & Biology, *36th & Spruce Sts., Philadelphia, Pennsylvania* 19104 (P50 NS 11036-07)

Multiple sclerosis is one of the most common chronic neurologic diseases in the United States today. More than 100,000 patients are severely crippled by this disorder. The cause of the disease is not known and there is no effective long-term treatment. Since Charcot originally described multiple sclerosis more than 100 years ago, neurologists and neuropathologists have noted an expanded spectrum of clinical and pathologic variation from individual to individual afflicted with multiple sclerosis. In the 1950's, epidemiologic studies indicated both high and low-risk prevalence areas for multiple sclerosis. Further studies on migrant populations suggested that multiple sclerosis was acquired in childhood although clinical disease is not manifested until adult life. While these data were accumulating, the concept of the 'slow-virus' neurologic disease was developing, with apparent incubation periods of many months or years. The concept that multiple sclerosis might possibly be a viral disease with a long incubation period was an attractive hypothesis born by the blending of fruitful multiple sclerosis epidemiologic studies with the knowledge that the spongiform encephalopathies (including human Jakob-Creutzfeldt) were transmissable and also that other chronic neurologic diseases of man such as subacute sclerosing panencephalitis (SSPE) and progressive focal leukocephalopathy (PML) were directly associated with virus infections.

EPIDEMIOLOGIC STUDIES OF IMMUNE FACTORS IN MS

R. Detels, University of California, Los Angeles Campus, School of Public Health, Dept. of Epidemiology, *405 Hilgard Ave., Los Angeles, California* 90024 (R01 NS 10186-08)

The objective of this grant was to investigate the pathopoiesis of multiple sclerosis (MS) by conducting five studies using two populations of MS patients, one in a high prevalence area and one in a lower prevalence area. These studies include a cohort study of the natural history of MS in the two areas; an immunologic study of changes in immune status, clinical course and environmental exposures; a genetic study of families with multiple cases of MS; and a case-control study of patients and susceptibility matched siblings. Studies completed to date have suggested the existence of a multiple sclerosis susceptibility gene located on the sixth chromosome and a relationship between haplotype and mean measles titers in MS patients and their normal siblings. Data from the immunologic study suggest that patients have higher mean antibody titers and impaired cell-mediated immunity to measles.

The relationship of immune differences to changes in clinical status and the relationship between immune responses and genetic types will be further studied; the rate of progression to disability, mortality and other factors will be compared between the two cohorts; and analysis of the case-control study will determine factors which are associated with disease.

STROKE MORTALITY STUDY

F.D. Weinfeld, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. of Neurological & Communicative Dis. & Stroke, Disease Statistics Surveys Section, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 NS 02341-01 OBE)

This is a demographic study of stroke mortality. It undertakes to explore the potential biases associated with the assessment of age-specific death rate trends based on stroke deaths during the period 1950 to the present. Trends by sex, race, and specific ICDA categories of stroke for these age-specific groupings will be produced and assessed. The limitations of the data, the underlying assumptions of the analysis, and the implications of the findings will be considered available on multiple causes of death, an analysis will be undertaken to compare these more complete data with the primary cause of death data which have been used heretofore.

CLINICAL AND VIRAL STUDIES OF SUDDEN HEARING LOSS

W.R. Wilson, Harvard University, Boston Campus, Massachusetts Eye & Ear Infirmary, Dept. of Otolaryngology, *243 Charles St., Boston, Massachusetts* 02114 (R01 NS 15629-01)

The goal of this proposal is to achieve an increased understanding by means of a detailed clinical study of sudden hearing loss (SHL), a relatively common disorder with an attack rate of about 15/100,000 population per year. This syndrome affects all ages and sexes, and its principle causes probably include viral infections, cochlear membrane rupture, and vascular occlusion.

Our objectives will include a continuation of an ongoing prospective clinical study at Massachusetts Eye and Ear infirmary which currently attracts 30-35 new patients annually. However, we would extend our patient sample through collaboration with Dr. Frederick Byl at the Kaiser-Permanent Group referral center in Oakland, CA and Dr. Phillip Sprinkle, West Virginia Univeristy, Morgantown. The prospective clinical study planned in this proposal will assess the relationship of idiopathic (I)SHL to seasonal, genetic, environmental as well as occupational factors by use of a thorough patient history obtained on standardized questionnaire. By means of medical examination to include an otologic evaluation, audiogram, ENG, x-ray, routine laboratory studies, and when possible, electrocochleography; we hope to assess the role of underlying medical conditions such as viral infections, diabetes and previous ear disease in ISHL. Also, these procedures will aid in our further classification of the causes of ISHL. Another objective is the serological evaluation of paired sera obtained from 45 patients is banked at -70 degrees C in preparation for analysis. Finally, we will continue an ongoing double-blind clinical study of a potentially beneficial treatment that includes steroids and placebo. Currently 65 patients are enrolled in Oakland and Boston. All data generated from the above studies is entered on a standardized data form for statistical analysis at the Health Sciences Computing Facility, School of Public Health, Harvard University. The result of such an inter-institutional collaborative clinical and laboratory study will be a better understanding of the etiology, classification, and treatment of ISHL.

CEREBROVASCULAR CLINICAL RESEARCH CENTER

J.P. Whisnant, Mayo Foundation, *200 1st St. S.W., Rochester, Minnesota* 55901 (P50 NS 06663-13S1)

Studies of stroke in the population of Rochester, Minnesota, have included a study of subarachnoid hemorrhage (SAH) in which it was determined that the average annual incidence rate for SAH increases with age to the oldest age group. There has been no change in the average annual incidence rate over the 30 years of the study. A study of primary intracerebral hemorrhage showed a decreasing average annual incidence rate over the 32 years of the study and showed that 89% of the patients with primary intracerebral hemorrhage had prehemorrhage hypertension. For one portion of the study, it was shown that anticoagulant therapy contributed to an increased incidence rate of intracerebral hemorrhage.

A prospective study of asymptomatic carotid bruit continues. Among 284 patients enrolled in the study, 4 have had cerebral infarcts, 3 have had definite TIA's and 4 possible TIA's. Two have died from myocardial infarction. Twenty-five have undergone a major surgical procedure without complication. A study of the outcome of patients who have had carotid transient ischemic attacks and who have had endarterectomy continues. We are also conducting a study of the results of treatment of subarachnoid hemorrhage and comparing the surgical management with the natural history of the disease.

Computerized tomography study of stroke includes a statistical analysis of EMI head scan data, a computerized tomographic and radionuclide study of stroke, an analysis of the basal ganglia region by computer techniques and a correlation of EEG exam with CT scan.

AN INTERNATIONAL SYMPOSIUM ON STATUS EPILEPTICUS

A.V. Delgado Escueta, University of California, Irvine Campus, California College of Medicine, Continuing Medical Education Program, *Irvine, California* 92664 (R13 NS 16171-01)

Clinical and Basic Neurosciences have developed new information on the clinical and molecular-membrane consequences of repeated seizures and status epilepticus. The effects of convulsive and non-convulsive status epilepticus on the phospholipid and protein arrangements of the synaptic membrane, on protein synthesis, second messengers, protein phosphorylation, ion transport, energy metabolism and brain ontogeny are presently under investigation by neuroscientists from various continents. This proposal requests support for a workshop to be held in March 1980 to provide a forum for interaction between these basic scientists and neurologists concerned with the treatment of status epilepticus. Approximately 45-50 participants will be invited and the manuscripts presented will be published. The objective of the workshop is to encourage translation of basic cellular and membrane information to the bedside setting and to stimulate research on the epidemiology, neuropathology and new treatment of convulsive and non-convulsive status epilepticus.

HEREDITARY ASPECTS OF THE EPILEPSIES

M.L. Rivas, Oregon State Higher Education System, University of Oregon Health Sciences Center, Good Samaritan Hospital Medical Center, Division of Medical Genetics, *1015 N.W. 22nd Ave., Portland, Oregon* 97210 (R01 NS 15820-01)

The objective of this study is to facilitate investigations into the genetic etiology of the epilepsies with emphasis on the spike-wave epilepsies and, in particular, petit mal absence. We propose to study the genetic transmission of these disorders through intensive studies of kindreds ascertained through a proband with a verified epileptic condition.

The study utilizes two unique resources namely, (1) clinical records on 4,000 patients with a seizure disorder who were evaluated at the principal (and for a long time, only) neurological referral center in the Northwest during the period 1938 to 1963 and (2) EEG records on 8,000 individuals tested in the same period of time. Availability of these records permits the record linkage of clinical, laboratory (EEG) and genetic information.

Probands will be selected from individuals evaluated in the Child Neurology Clinic (Epilepsy Center of Oregon), the Genetics Clinic (UOHSC) or in private practice and from individuals evaluated in the Neurological Clinic between the years 1938 and 1963. Systematic collection of clinical, genetic and laboratory (EEG) data will be extended to first, second and third degree relatives of probands. Special emphasis will be placed on record linkage of families to insure completeness and accuracy of pedigree and clinical information. The body of data thus generated will be the basis of more extensive family/genetic studies and be subjected to rigorous genetic analyses and tests of goodness of fit to various genetic models (hypotheses) using recently developed, statistically powerful, computer-adaptable methods.

RISKS AND BENEFITS OF THE DECLINE IN ESTROGEN USE BY POSTMENOPAUSAL WOMEN

Y.Y. Palesch, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Epidemiology Demography & Biometry Program, *9000 Rockville Pike, Bethesda, Maryland* 20205 (Z01 AG 03000 EDBP)
OBJECTIVES/ISSUES ADDRESSED: Review the trends in estrogen use in the past decade by peri- and postmenopausal women. Discuss the current status of risks and benefits of estrogen use.
APPROACH/METHODOLOGY: Abstract data on estrogen drug appearance from National Disease and Therapeutic Index volumes (1970-1978). Mortality and incidence data of endometrial cancer for the U.S. is also collected. Review current literature on estrogen as risk or beneficial factor.
MAJOR FINDINGS: A drastic decline in estrogen drug appearances is observed during 1975-76 following the publication of several case-control studies linking estrogen use with endometrial cancer.

MARITAL, SEXUAL AND SOCIAL FACTORS IN AGING

C. Martin, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Human Performance Section, *Baltimore, Maryland* 21224 (Z01 AG 00018-13 CPB)
Systematic data concerning sexual, marital and social experience were obtained by structured interviews with males taking part in the Baltimore Longitudinal Study of Aging. During the year it was found, in collaboration with Dr. S.M. Harman, that frequency of sexual expression in 60-79 year-old respondents showed a small but significant relationship to level of serum testosterone and that levels of basal sex steroids remained largely unaffected by age. At present, an analysis is underway in which respondents with and without a history of coronary heart disease are being compared in relation to a variety of personal and behavioral experiential attributes, as revealed by interview, for evidence of etiologic processes.

INVESTIGATIONS OF OSTEOARTHRITIS AND BONE LOSS

C.C. Plato, U.S. Dept. of Health & Human Services, Public Health Service, National Inst. of Health, National Inst. on Aging, Human Performance Section, *Baltimore, Maryland* 21224 (Z01 AG 00022-03 CPB)
Osteoarthritis and bone loss are the two principal age related changes of the human skeleton. Even though these changes are considered inherent to aging, they may result in incapacitating ailments. The advanced cases of osteoarthritis (degenerative joint disease) produce severe restriction of movement associated with pain. Advanced bone loss may result in osteoporosis and frequent bone fractures. Most prominent are vertebral compression fractures and fractures of the femoral neck.
This project deals with the epidemiological, genetic and longitudinal aspect of osteoarthritis and bone loss among (1) the participants of the Baltimore Longitudinal Study, (2) in a sample of normal Guamanians (Chamorros), and (3) among patients afflicted with Amyotrophic Lateral Sclerosis/Parkinsonism Dementia Complex of Guam.

PROGRAM PROJECT IN BIOMEDICAL ASPECTS OF AGING

J.W. Rowe, Harvard University, Boston Campus, Beth Israel Hospital, Dept. of Medicine, *330 Brookline Ave., Boston, Massachusetts* 02215 (P01 AG 00599-03)
Recent cross-sectional studies in man have identified two important alterations in the secretion of AVP with advancing age. These are: (1) augmented AVP secretion in response to osmotic stimulation and (2) escape from the inhibitory influence of intravenous ethanol on AVP secretion. The studies outlined in this proposal will determine the influence of age, volume status and plasma AVP concentration on the volume of distribution and metabolic clearance rate of exogenous vasopressin.
Several aspects of the influence of age on AVP secretion will be studied. These include clarification of the influence of volume expansion and depletion on the previously documented increased osmoreceptor sensitivity with age, the impact of aging on response to hypoosmolar inhibition of AVP release, and the impact of age on the response to several non-osmolar stimuli of AVP secretion. Non-osmolar stimuli to be employed are: (1) upright posture and (2) pharmacologic stimuli (apomorphine, luteinizing hormone releasing factor (LHRH) and thyrotropic releasing factor (TRH).

USE OF DEATH STATISTICS TO MEASURE MORTALITY OF AGED

I. Rosenwaike, University of Pennsylvania, School of Medicine, Dept. of Research Medicine, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (R01 AG 01115-02)
This is a study that will consider the effect that inaccurate statement of age on the death certificate and in the census record has on the published death rates for the very elderly, and in turn, on the life table values for this population. Particular emphasis will be given to examining differentials in accuracy by race and sex. By using a procedure known as the 'method of extinct generations', a method that permits the reconstruction of 'extinct' population cohorts from the death statistics for a series of years, new estimates of the United States population 85 years of age and over will be prepared for the years 1951 through 1965 for single years of age by sex and race. The resulting estimates for the periods around the 1950, 1969 and 1970 censuses will be compared with decennial census statistics.
A series of age-specific death rates will be computed from the derived populations and these will be compared with official data for the United States. The new series of death rates will be utilized in the preparation of life tables for the elderly, and the values obtained will be compared with the official current United States life tables. Trends in mortality and survival among the extreme aged population will be analyzed.
BIBLIOGRAPHIC REFERENCES: Ira Rosenwaike: A New Evaluation of United States Census Data on the Extreme Aged, Demography, May 1979, in press.

SPECIAL INITIATIVES RELATED TO DEMENTIA

R. Katzmann, Yeshiva University, Bronx Campus, Albert Einstein School of Medicine, Dept. of Neurology, *1300 Morris Park Ave., Bronx, New York* 10461 (R21 AG 01184-02)
Senile dementia of the Alzheimer type (SDAT), the major cause of dementia among the elderly, is a growing health problem. Although much has been learned about the pathophysiology of this disease, little is known about etiological factors. We propose to seek information about specific genetic, environmental, and metabolic risk factors by carrying out a cross-cultural case control study of SDAT. We will utilize an epidemiological interview together with studies of serum haptoglobins as linked genetic markers; immunological changes manifested by lymphocyte responses and serum immunoglobulins; serum antibodies to choline acetyltransferase, and parathormone status. One aspect of the social impact of SDAT will be studied by investigating techniques adopted by families for coping with an afflicted family member.

CASE-CONTROL STUDY OF PRESENILE AND SENILE DEMENTIA

A. Heyman, Duke University, School of Medicine, Dept. of Medicine, *Box 3711, Durham, North Carolina* 27710 (R21 AG 01186-02)
The present proposal is a collaborative case-control study of a small cohort of patients diagnosed as having, on the basis of carefully established clinical criteria, presenile or senile dementia of the Alzheimer's type. Information will be obtained regarding factors possibly related to the development of this illness from these patients and from matched control subjects by means of a structured epidemiologic interview, by analyses of serum and cerebrospinal fluid for viral antibodies and for increased concentrations of aluminum and other metallic ions and by detailed family history searching for evidence of genetic defects. The natural history of the disorder and the correlation between the progressive mental changes, the electroencephalographic abnormalities and the changes in computer tomography of the brain will also be studied.

DEPRESSION, INFORMATION PROCESSING AND AGE

P.M. Lewinsohn, Oregon State Higher Education System, University of Oregon, School of Liberal Arts, Dept. of Psychology, *1472 Kincaid St., Eugene, Oregon* 97401 (R21 AG 01449-01)
Two separate projects are proposed. Project 1 ('Epidemiology of Depression in the Elderly') is a longitudinal prospective study of a representative sample of 900 elderly persons. Subjects are assessed on a wide range of measures at point of entry into the study. They will be followed for two years during which time their depression level will be monitored on a monthly basis. Clinical assessments will be done on subjects who become depressed. Four types of hypotheses will be tested: 1) What are the distinguishing characteristics of elderly persons who become depressed? 2) What are the distinguishing characteristics of elderly persons who are depressed? 3) What are the distinguishing characteristics of elderly persons who are depressed and who

recover? 4) What are the distinguishing characteristics of elderly persons who have a history of having been depressed earlier in life?

Project 2 has three objectives: 1) To adapt an existing conceptualization of the key ability factors underlying cognitive performance to the study of the aging. 2) To use the measurement devices constructed as per objective 1 to evaluate the effects of cardiovascular conditioning on the cognitive behavior of elderly depressed and elderly non-depressed Ss. 3) The measurement devices will be used to assess cognitive functioning as a function of age.

2.1220,

ACCURACY OF DEATH CERTIFICATE AGES FOR THE EXTREME AGED

I. Rosenwaike, University of Pennsylvania, School of Medicine, Dept. of Research Medicine, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (R01 AG 01550-01)

Observers have repeatedly questioned the accuracy of age information for the extremely aged population of the United States. Inaccurate statement of age on the death certificate will have an effect on the published death rates for the very elderly.

The proposed research will attempt to verify the reporting of age on the death certificate among persons in the 'extreme aged' population. A sample of about four thousand decedents around 1970 who were reported to have been 85 years old or over will be selected from the death certificates filed in the cooperating states. Since record check with the birth certificate in most instances is not possible, the record linkage will be with the listing in the well - indexed 1900 census, conducted when the decendent presumably was a youth or young adult. The motive to exaggerate age attributed to the elderly would not have been present at this early period. Effort will be made to correct age on the death certificate on the basis of tho 1900 census records. The 'adjusted' distribution of deaths by age around 1970 so derived, will permit the computation of corrected death rates and life tables. These data may then furnish a basis for improving mortality statistics at older ages, and for evaluating the quality of census data. In addition, they may provide a better appreciation of the basic causes of the anomaly of the cross-over of nonwhite mortality to lower levels than white mortality at the upper age range.

THE U.S. MORTALITY DECLINE - EVIDENCE FROM CENSUS DATA

E.M. Crimmins Gardner, Rutgers the State University of New Jersey, Camden Campus, College of Arts & Sciences, Dept. of Sociology, *406 Penn St., Camden, New Jersey* 08102 (R01 AG 02089-01)

The purpose of the proposed research is to estimate levels and trends in U.S. mortality in the last half of the nineteenth century. In addition to estimating levels and trends at a national level the proposed project will estimate mortality differentials for regions of the country, rural and urban areas, and nativity groups. The project will also examine the determinants of mortality levels and change during this period. Data on nutritional levels and the provision of public health provisions will be related to mortality conditions. Mortality data available in the federal census will be used in this research. This research will add to current knowledge on the demographic transition by clarifying the American experiece and by testing a number of theories of causation of the decline in mortality in the now developed world.

2.1222,

MORTALITY OF OLDER MALES IN INTERNATIONAL PERSPECTIVE

M.H. Brenner, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Health Services Administration, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 AG 01833-01)

The objective of the proposed research is to explain the relatively poor mortality experience of older males in the United States as compared with males and females in other industrialized countries, and with U.S. females. In accomplishing this objectve it is necessary to account for international differences in mortality rates over age 45 among males, among females, and among the ratios of male to female mortality in industrialized countries.

The overall approach relies, first, on comparative time-series analyses of the effects of economic development and fluctuations in male and female mortality rates over age 45 for each of 25 industrialized countries during 1920-1976. These countries are located in Western Europe, North America, and Australasia. Additional analyses then attempt to interpret the findings on the differential impact among the industrialized countries of broad economic changes on mortality trends of older males and females. These multivariate analyses examine the extent to which factors cited in the literatures on aging, social demography, and psychological stress explain the differential impact of economic development on mortality trends for the older population. In this study, controls are used for the contributory effects of environmental and biological influences by including such influences in the general multivariate models of total and cause-specific mortality.

The principal variables which are hypothesized to explain differential international mortality rates by sex among the older populations are: income, employment status - especially retirement and unemployment, occupation, educational attainment, marital status, including widowhood and family composition, parity of women, ethnic heterogeneity, institutionalization and other isolation of the older populations, and availability of health care.

2.1223,

PROSPECTIVE STUDY OF NUTRITION IN THE ELDERLY

J.S. Goodwin, University of New Mexico, School of Medicine, Dept. of Medicine, *University Hill N.E., Albuquerque, New Mexico* 87131 (R01 AG 02049-01)

A substantial proportion of old people in this country have dietary intakes of protein, calories, vitamins, and iron that are below the recommended dietary allowances. It is not known, however, what effect this 'subclinical' malnutrition in old people has on their physical health and life expectancy. In this proposal we will follow 250 healthy old people over a five year period. The nutritional status of these subjects will be evaluated yearly by clinical exam, a three day dietary record, and biochemical analysis of blood samples for total protein, albumin, transferrin, serum iron and iron binding capacity, vitamins A, C, B12, riboflavin, thiamine, pyridoxine, folic acid, copper, zinc, cholesterol, and HDL-cholesterol. We will then examine whether deficiencies of these nutrients as measured by dietary records and by biochemical analysis predisposes subjects to increased morbidity and mortality during the five year follow-up period. These healthy old people will also be evaluated immunologically with skin tests, and in vitro mitogen responses. We will examine whether subclinical malnutrition results in depressed immune function.

The other major aspect of this study will be to prospectively study the impact of major life crises on the nutrition of our subjects. We will study the effects of hospitalization, change in living conditions, and bereavement on the dietary intakes of these subjects. We will determine which life crises cause a drop in dietary intake and how long dietary intake stays down. We will also psychologically test these subjects after the 'life crises' to determine the relationship between depression and nutritional status.

2.1224,

AGING AND HETEROGENEITY IN MORTALITY RISKS

K.M. Weiss, University of Texas, Health Science Center at Houston, Graduate School of Biomedical Sciences, *P.O. Box 20334, Houston, Texas* 77025 (R01 AG 01028-02)

This study will examine risk heterogeneity in age patterns of mortality by cause at various levels of population. Risk of death from major causes of mortality, by age, will be parametrically described, taking account of competing causes. This will be related to the theory of human biological aging. Risk-rate parameters will be characterized statistically, including their sample variances, their geographic and temporal clustering, and their inter-cause correlations. This will first be done on subdivisions of nations using data from Chile and Texas to look for more local effects and variatons. Finally, risk functions will be estimated for the Mexican-Americans of Laredo, Texas. Here risk assessment and studies of risk heterogeneity will be done on genealogical data so as to examine the genetics of longevity as they relate to specific causes of death and the age at which they occur, and cluster, in families.

2.1225,

DETERMINANTS OF AGING AMONG SEVENTH-DAY ADVENTISTS

J.W. Kuzma, Loma Linda University, School of Health, Dept. of Biostatistics & Epidemiology, *Loma Linda, California* 92354 (R01 AG 01582-01)

Seventh-day Adventists (SDAs) are members of a conservative Protestant denomination who neither drink nor smoke; 41 percent are vegetarians. Their age distribution shows a significant proportion of older persons. In 1958, a longitudinal study of California SDAs was mounted to investigate the association of life habits with mortality and life expectancy. The study demonstrated that SDAs had a longer life expectancy than the general population and for most cancer sites had significantly lower mortality rates. Since 1974, a larger group of SDAs has been studied in depth to determine morbidity from major disease and to ascertain which factors in their unique lifestyle associate with their apparent longevity and reduced disease risk. The two separate studies have some 20,000 common enrollees; however, thier records have never been linked.

Objectives of this research are five-fold: 1) to ascertain the living-dead status of persons originally enrolled and link their records with current enrollees, thus providing a 20-year mortality follow-up: 2) to analyze long-term longitudinal results in terms of the epidemiological correlates of aging; 3) to compare mortality statistics of the SDA population with a separate population from the general public which ahadbeen independently and concurrently studied; 4) to determine which life habits are most associated with a high quality of life in an aging population; and 5) to learn whether the SDA's favorable mortality is due to selective factors or results from the unique, if variable, practice of the group.

The methodology involves a computerized probability model to link data files of the two studies, along with trained field workers tracing church membership records. In a substudy, life quality will be measured in 350 SDAs over 74 and 400 appropriate controls. Investigation into the longevity and quality of life of the oldest members of a long-lived group seems to be appropriate at a time of steady increase in the number of elderly persons in the general population.

2.1226,

PERSONAL PATTERNS PREDICTIVE OF DISEASE OR DEATH

C.B. Thomas, Johns Hopkins University, School of Medicine, Dept. of Medicine, *725 N. Wolfe St., Baltimore, Maryland* 21205 (R01 AG 01760-01)

The Precursors Study is a long-term prospective investigation of the characteristics of a cohort of 1,337 Johns Hopkins medical students, in classes graduating in 1948 through 1964, to determine youthful predictors of premature disease or death. Now for the most part physicians aged 40 to 59, their health and that of their parents are being followed annually by mail. By 1977, over 200 subjects had been affected by one or more major disorders.

Studies to date, on data obtained from individuals while they were medical students, have identified a number of specific, separate characteristics which distinguish between subjects who remain healthy and those who have died prematurely or become diseased, and between subjects with one form of disorder and those with another.

These separate items represent four different categories of data: Biological (e.g., mother's age at subjects' birth); Physiological (e.g., resting diastolic pressure, resting heart rate); Metabolic (e.g., relative body weight, cholesterol level); and Psychological (e.g., depression, anxiety and anger under stress, closeness to parents, family demonstrativity, pathological unconscious psychic processes and content). The aim of future studies is to go beyond the present listing or aggregation of separate characteristics, and

to organize material in the data base in such a way as to portray the individual as a biological-cultural organism with a characteristic core, a long-range style in experiencing, shaping and adapting to his successive life events. The time span since the original data were collected is now 14 to 30 years, so much added data have accumulated on the life styles and life events of both healthy and unhealthy subjects.

PREPARE BOOK ON BACTERIAL INFECTIONS OF HUMANS

A.S. Evans, Yale University, School of Medicine, Dept. of Epidemiology & Public Health, *333 Cedar St., New Haven, Connecticut* 06510 (R01 LM 03299-01)

The purpose or the request is to co-edit a book on 'Bacterial Infections of Humans. Epidemiology and Control' in conjunction with Dr. Harry A. Feldman, Professor and Chairman, Department of Preventive Medicine, College of Medicine, Upstate Medical Center, Syracuse, N.Y. This book would be a companion volume to Viral Infections of Humans. Epidemiology and Control, A.S. Evans, Editor, Plenum Publishing Corp., 1976.

Most texts on infectious diseases concentrate either on the basic aspects of the agent (i.e. microbiology) or on the host response (clinical infectious diseases). The proposed book would emphasize epidemiology and control and bring together those aspects of the agent, the pathogenesis of the infection, and the patterns of host response necessary to an understanding of the dynamics of the infection both in the community and in the individual. After 2 introductory chapters one on general epidemiological concepts and one on surveillance, all the major infectious agents in the genus 'Bacillus' of importance in the U.S. would be presented alphabetically in individual chapters by authorities in the field.

HUMAN POPULATION LABORATORY FOR EPIDEMIOLOGIC STUDIES

A.C. Hollister, State Dept. of Health, Occupational Health Section, *2151 Berkeley Way, Berkeley, California* 94704 (R01 HS 00368-15S1)

The long-term objective of the Human Population Laboratory is to articulate relationships between social, psychological and physical patterns of living and states of individual health. In pursuit of this broad objective, the staff of the HPL has conducted: (1) a 1965 Baseline Survey, in which almost 7,000 randomly selected adult residents of Alameda County, California, provided answers to a 23-page questionnaire concerning health status and health practices; (2) a continuous follow-up of the mortality of the original sample respondents; (3) a 1974 Longitudinal Follow-Up of the surviving respondents, to measure individual changes in health status and self-reported occurrence of life-crisis events in the intervening period; (4) a 1974 Survey of approximately 3,000 randomly selected current residents of the County, to provide community trend information as well as current information on the utilization of health care facilities, unmet needs and sources of satisfaction and dissatisfaction; (5) a 1975 special supplementary survey of residents in neighborhoods with high concentrations of Spanish American families.

2.1230,

CLAIMS-FILE RESEARCH - PEDIATRIC HEALTH CARE QUALITY

W.A. Ray, Vanderbilt University, School of Medicine, Dept. of Preventive Medicine, *21st Ave. S. & Garland, Nashville, Tennessee* 37232 (R01 HS 03222-02)

The methodologies employed in health and health services research depend heavily upon the sample survey as a source of data. The expense, lack of precision, and time-consuming nature of this approach are accepted in lieu of alternatives. With the emergence of a computer technology that can manipulate very large data-bases, new sources of data are available. The massive investment for administrative data processing in the health care delivery programs (Medicare and Medicaid) can be exploited for health services research.

This proposal links large administrative data-files to investigate a specific topic: the descriptive epidemiology of psychotropic drug prescribing in large, heterogeneous, defined populations of children and prescribing physicians. The estimated 2 million prescriptions for the 200,000 children eligible for Tennessee Medicaid benefits over the 5-year period 1973-1978 will be reviewed. The analysis for children will encompass prescription incidence rates and utilization ratios, frequent use of psychotropic drugs, exposure to multiple agents, doctor shopping, and 5-year trends. Physician training and characteristics of current practice will be correlated with prescribing of psychotropic drugs. The association of the mal-prescribing of antiinfectives with increased prescribing of psychotropic drugs will be tested. This research will supply currently unavailable data for policy purposes. It has implications for improving quality and lowering cost of government-provided medical care for children, improving physician prescribing practices and the development of health services research technology.

2.1231,

EVALUATION STUDY OF AN ALTERNATIVE BIRTHING CENTER

G. Baruffi, Johns Hopkins University, School of Hygiene & Public Health, Dept. of Maternal & Child Health, *615 N. Wolfe St., Baltimore, Maryland* 21205 (R01 HS 03762-01)

Over the past few years, increasing numbers of women have elected to deliver outside the hospital in maternity centers or at home. The objective of this study is to evaluate the physical safety of an 'out-of-hospital' maternity center. Two questions are addressed by this epidemiological prospective non-concurrent study: 1) Do maternal and neonatal outcomes of two populations comparable on sociodemographic and medical-obstetric risk differ in two institutions with different approaches to maternity care? 2) Does the process of transfer from one institution to another involve increases risk to sick pregnant women and newborns?

The study populations, selected from Booth Maternity Center and Thomas Jefferson University Hospital, both located in Philadelphia, Pennsylvania, will be matched by distribution for the investigation of the first question and by pair for the investigation of the second. Matching variables will be: race, maternal age, education, gravidity, and previous pregnancy loss. Pregnancy outcomes process of care, medical-obstetric risk and sociodemographic characteristics will be analyzed by univariate and multivariate statistical techniques.

AN ANALYSIS OF DATA FROM THE LOUISVILLE CHILDHOOD LEAD POISONING CONTROL PROGRAM

Unknown, Louisville & Jefferson City Dept. of Public Health, *Louisville, Kentucky* (H-2550RG)

This is a continuation of a joint HUD/HEW demonstration project underway since 1976. In 1978 the tasks of establishing an operating model program were completed. The data from files of the 14,000 children screened since 1974 was coded and entered onto a computer data base. In this fiscal year an analysis of this data base will be continued to determine those characteristics (child, housing, air, plumbing) associated with higher lead-in-blood levels and whether long-range effects of these elevated levels are detectable.

SUPPORTED BY U.S. Dept. of Housing & Urban Development, Office of Policy Development & Research funds n.a.

INTERRELATIONSHIP BETWEEN LEAD IN THE DWELLING UNIT AND BODY LEAD BURDEN IN PRESCHOOL CHILDREN

Unknown, Ohio State University, Columbus Campus, Childrens Hospital, Research Center, *561 S. 17th St., Livingston Pike, Columbus, Ohio* 43205 (H-2897)

This project will compile, code, edit, and analyze health and housing data files from a local child screening program (Columbus, Ohio) to determine the relationships that exist between blood lead levels and housing, demographic and biochemical factors. Staff from Children's Hospital Research Foundation and Ohio State University will attempt to determine the nature and extent of the lead poisoning problem in Columbus, Ohio by a retrospective study of the existing data from HEW-sponsored screening program which has been underway since 1972.

2.1234,

ASBESTIFORM MINERALS

M. Ross, U.S. Dept. of the Interior, Geological Survey, Geologic Div., *12201 Sunrise Valley Dr., Reston, Virginia* 22092 (9710-01991)

OBJECTIVES: Assess the epidemiological, mineralogical, and petrological studies that have been made which can contribute to our knowledge of the role naturally occurring minerals play in the production of lung and intestinal cancer and mesothelioma in the U.S. population. Initiate mineralogic studies which may give an insight into the 'asbestos and health' problem.

SUPPORTED BY U.S. Dept. of the Interior, Geological Survey, Geologic Div. $79,630

2.1235,

ARE PUBLIC AND RECREATIONAL WATER SUPPLIES IN MONTANA SAFE FROM YERSINIA ENTEROCOLITICA GASTROENTERITIS

M.J. Nakamura, University of Montana, School of Arts & Sciences, Dept. of Microbiology, *770 Eddy St., Missoula, Montana* 59801 (A-104-MONT)

BACKGROUND: There is increasing evidence that Yersinia enterocolitica may cause water-borne gastroenteritis. An outbreak in Montana of unknown origin may have been caused by this organism. There is virtually no information on the prevalence of this pathogen in the public and recreational waters of Montana.

OBJECTIVES: To develop adequate bacteriological methods for the rapid and accurate identification of Y. enterocolitica. To establish routine laboratory procedures for quantification of this organism in water samples. Varied sampling stations will be established. They will in all probability include camp grounds, picnic grounds, and recreational areas. Initially, the sampling will be made from tap water, which is generally assumed by the public to be potable. Samples will be taken periodically during the winter months and extensively during summer months. If certain water sources appear to be contaminated and thus a potential health hazard to the water consumer, proper agency officials will be contacted so that corrective measures may be instituted. Other enteric pathogens will also be surveyed. Eventually this would lead to a continuous surveillance procedure to safeguard the health of visitors to recreational areas. If time permits serotyping of Y. en-

terocolitica isolated will be attempted to establish an epidemiological pattern of the different serotypes.

2.1236,

THE INVESTIGATION OF NATURAL 222RN AND 225RA IN GROUNDWATER IN MAINE AND ADJACENT AREAS AND ASSESSMENT OF RELATED HEALTH EFFECTS

C.T. Hess, University of Maine, Orono Campus, School of Arts & Sciences, Dept. of Physics, *36 Winslow Hall, Orono, Maine* 04473 (A-045-ME)

The investigation will study the association of 222Rn and 226Ra with geology and hydrology in Maine areas which are suspected of having high levels of these elements. The assessment includes comparisons with water chemistry, as well as hydrology, recharge time, age of water, and develops a general understanding of geographical distribution and controlling parameters for 222Rn and 226Ra. The study tests for correlation of high concentrations in water with health effects (lung cancer, stomach cancer, bone cancer, etc.).

TRAVEL AND ACCIDENT DATA

J.P. Mills, State Dept. of Highways & Transportation, *1221 E. Broad St., Richmond, Virginia* 23219

The purpose is to provide timely, consistent and complete nationwide data concerning the number of fatal and injury accidents as they relate to the highway system. The analysis and summary of these data will provide the sound traffic accident information needed for improved evaluation and guidance of the continuing state, local and national highway safety programs.

Fatal and injury accident rates on Federal-Aid and other highway systems study referred to as TA-1 report annually. This is a study done for the Federal Highway Administration; Department of Transportation. Completion date is June of each year.

COOPERATIVE AGREEMENT FOR EPIDEMIOLOGY RESEARCH CENTER

E.P. Radford, University of Pittsburgh, Graduate School of Public Health, Dept. of Epidemiology, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (R806815-01)

By a cooperative research center agreement between of the EPA and the University of Pittsburgh, an Environmental Epidemiology Center would be established at the University's Graduate School of Public Health. Its primary goals would be to: (1) bring together a wide range of school, university, community, regional, national, and even international resources to plan and perform research in the field of environmental epidemiology and contributory and related fields; (2) provide specialized assistance to the EPA; (3) provide means for scientists in these fields from outside the university to contribute to Center research, service, and educational activities; and (4) provide advanced graduate and post-graduate training in these fields. An executive committee, comprised of Dr. Edward P. Radford, Director and Professor of Epidemiology, Dr. Philip E. Enterline, Associate Director and Program Coordinator for Biometry, Program Coordinators for Environmental Epidemiology of Chronic Disease, Environmental Toxicology, Air and Water Pollutant Effects, and Environmental Radiation Effects (Drs. Lewis H. Kuller, Yves C.E. Alarie, Julian B. Andelman, and Neil Wald, respectively), Dean and Professor of Epidemiology Herschel E. Griffin, and Directors of EPA Health Effects Research Laboratories, would govern the Center with the assistance of a National Advisory Board having EPA, Center, and 'external' representation. A variety of mechanisms having optimal flexibility to respond to ever-changing needs and circumstances would be used to address needs of the EPA and field of environmental epidemiology and assistance needs of the EPA. In addition to research and service activities, Center Fellows, Visiting Scholars, EPA Visitors/Exchange, and Symposium Series Programs would be established. The Center would also provide graduate- and post-graduate-level training, and perhaps new courses and educational programs in environmental epidemiology would be established through the Center and School.

2.1242,

DEVELOPMENT AND EVALUATION OF AN ENVIRONMENTAL DATA ANALYSIS SYSTEM

L. Milask, Sigma Data Computing Corp., *12730 Twinbrook Pkwy., Rockville, Maryland* 20852 (79-0655)

OBJECTIVE: The objective of the IAG is to provide for collaboration in the development and application of the UPGRADE System to support analysis in the area of environmental health.

APPROACH: Databases dealing with such environmental health areas as populations at risk to air polluton, morbidity and mortality rates, and/or health care utilization will be investigated and appropriate variables added to existing databases. These data will be analyzed using the UPGRADE System and reports prepared.

PROGRESS: Investigation of databases has begun. Enhancements to the UPGRADE/EXTRACT System to allow for increased data capabilities are underway. Information on the SMSA level is being collected and morbidity rates are being calculated in preparation for a new database. New release 4.0 has been completed and is in operation. User's manual will be available by January 1980.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Monitoring & Technical Support $70,000

2.1243,

EPIDEMIOLOGICAL ASSESSMENTS OF THE RELATION BETWEEN SELECTED ENVIRONMENTAL VARIABLES AND AGE-ADJUSTED MORTALITY/MORBIDITY RATES

T. Darby, U.S. Dept. of Health & Human Services, Public Health Service, Office of Health Research Statistics & Technology, National Center for Health Statistics, *3700 East West Hwy., Hyattsville, Maryland* 20782 (07-01071)

OBJECTIVE: Develop methodologies to relate morbidity/mortality data to air and water quality data by county of SMSA.

APPROACH: Investigate use of data from NCHS surveys (HIS, HANES, Vital Statistics) in conjunction with environmental data. Apply correlational analysis, multiple regression, factor analysis, and mapping to determine small-area differences, geographic variations, or trends, possibly attributed to environmental variables.

PROGRESS: Creation of a file of age-adjusted and age-specific rates of acute and chronic conditions from Health Interview Survey aggregated over 5 years.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Monitoring & Technical Support $55,000

2.1244,

SAMPLE ANALYSES FOR ROCKY FLATS HUMAN BURDEN STUDY

W. Menzies, U.S. Dept. of Defense, Air Force, McClellan Central Lab., *1155th Tech. Ops. Squadron, McClellan A.F.B., Sacramento, California* 95652

OBJECTIVE: The principal objective of the study is to determine if those people who reside near the Rocky Flats Nuclear Weapons Facility have higher burdens of plutonium than the general population. This effort is to provide the sample analyses for this project.

APPROACH: Analyze samples collected by the University of Colorado Medical School using standard radiochemical techniques.

PROGRESS: As of March 10, 1980, 836 samples have been analyzed. total of 1,061 samples are to be analyzed for this project.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab. $35,500

2.1245,

ROCKY FLATS HUMAN BURDEN STUDY

J.C. Cobb, University of Colorado, Medical Center, School of Medicine, Dept. of Preventive Medicine & Comprehensive Health Care, *4200 E. 9th Ave., Denver, Colorado* 80262 (68-03-2915)

OBJECTIVE: To provide statistical and epidemiological analyses of the data from samples collected under this contract and analyzed under the Interagency Agreement with McClellan AFB. Data from these analyses will indicate if persons living near the Rocky Flats Nuclear Weapons Plant have increased body burdens of plutonium.

APPROACH: Samples were collected from autopsied humans by the University of Colorado Medical School in three geographical areas. The first area was within 0-25 Kilometers radius of the Facility; the second area was 25-50 kilometers radius of the Facility; and the third area was the remainder of Colorado east of the Rockies. Liver and lung tissues were analyzed for plutonium content.

PROGRESS: Preliminary results indicate that the plutonium activity levels in tissue samples from each collection area are within the activity levels expected from global fallout. Measurements of the 240 Pu/239 Pu isotope ratios indicate that several of the samples from the 0-25 and the 25-50 kilometers collection areas contain small quantities of weapons grade plutonium.

INHALED PARTICULATE MATTER NETWORK

R. Weaver, Systems Research & Development Corp., *3022 Chapel Hill Rd., P.O. Box 12221, Research Triangle Park, North Carolina* 27707 (68-02-2449)

Objectives are to expand current data handling capabilities and to process incoming data from the Inhaled Particulate Matter network.

Outputs are to be in the form of quarterly and annual reports summarizing the data.

Trial tests of current systems have been completed by the contractor and they can handle existing data formats. Systems analysis on siting expansion has been completed and programming has begun. Systems analysis on raw data file is scheduled to begin in August. To date the contractor is two weeks ahead of schedule.

PROGRESS: System analysis and programming efforts for maintenance of the system are complete. Work has begun for special report programs needed for quarterly and annual reports.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab. $50,000

2.1247,

DERIVE EXPOSURE/DOSE ASSESSMENT MODEL FOR INDIVIDUALS IN A POPULATION

S.K. Friedlander, California Inst. of Technology, School of Engineering, Dept. of Chemical Engineering, *1201 E. California Blvd., Pasadena, California* 91109 (68-03-0434)

OBJECTIVE/APPROACH: To report on a survey of the literature on exposure/dose models relating carcinogens in the environment and human exposure to them. An assessment will be made of the applicability of available models to environmental carcinogen transport and impact.

FINAL OUTPUT: The final output will be a report which will consist of a comprehensive survey of the literature on development and application of mathematical simulation models describing sources, environmental pathways, and exposure/dose relationships of environmental carcinogens. The applicability of one or more of these models will be tested and research identified as required.

PROGRESS: Proceedings on Conference on Chemical Carcinogens in the Environment in final editing prior to publication. Final report on models and applicability completed. Released for publication.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab. $0

2.1248,

DESIGN A SYSTEM FOR COST-EFFECTIVE ASSESSMENT OF ENVIRONMENTAL CARCINOGENS (#16)

G.B. Wiersma, U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab., *P.O. Box 15027, Las Vegas, Nevada* 89114

OBJECTIVE/APPROACH: 1. Serve as a mechanism for evaluating available monitoring system techniques to assess exposure of humans from environmental carcinogens. 2. Provide the basis for identifying potentially exposed populations to carcinogens in support of future epidemiological studies should they be desired. 3. Provide the data base needed for the development of a definitive exposure monitoring system in conjunction with epidemiological studies.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab. $848,700

2.1249,

RETROSPECTIVE EXPOSURE MONITORING FOR SELECTED ENVIRONMENTAL CARCINOGENS

G.D. Potter, U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab., *P.O. Box 15027, Las Vegas, Nevada* 89114

OBJECTIVE/APPROACH: Determine the availability and locate materials which can be analyzed for concentrations of selected chemicals. Suitable materials may include home or locally packaged foods, biological specimens, such as tree rings, soil cores, preserved plants and/or animals. The selection of suitable samples will be investigated. Methodologies for collection and analysis will be documented.

FINAL OUTPUT: A series of reports which can be used to estimate past exposure of populations to specific carcinogenic or toxic materials released from industrial or agricultural sources in specific impact areas.

PROGRESS: A preliminary study on tree rings has been completed and analytical data from neutron activation spectra of the rings for potential 'marker' materials transported with toxic substances is under way, and a report showing correlation between arsenic emission from a smelter and its concentration in annual rings from trees has been completed.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab. $0

2.1250,

ABSORPTION, DISTRIBUTION, AND EXCRETION OF ACTINIDE ELEMENTS BY DAIRY CATTLE

G.D. Potter, U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab., Exposure & Dose Assessment Branch, *P.O. Box 15027, Las Vegas, Nevada* 89114

OBJECTIVE/APPROACH: The purpose of this research is to provide input data for hazard assessment of areas contaminated by plutonium, uranium, and americium originating from nuclear testing activities, nuclear power plants, nuclear fuel reprocessing/fabrication facilities, and uranium extraction/fabrication activities. Since man consumes large quantities of dairy products and beef, evaluation of radiological hazards associated with actinide releases must include transport to man via the food chain from cattle which could ingest large quantities of these actinides. Dairy cows and goats are maintained in metabolism stalls and actinide elements are administered by oral or intravenous routes. Blood, milk, urine, and fecal actinide concentrations are determined daily until the animals are sacrificed for determination of tissue nuclide burdens. The actinides administered are in specific chemical/physical forms which include the forms found in the environment. A new study on the feeding of debris from old nuclear test sites to goats has been initiated in order to determine which of the long-lived radionuclides from the debris will be observed in tissues.

FINAL OUTPUT: Comparison of 238Pu and 239Pu metabolism in cows. Summary report comparing studies on plutonium, americium, curium and neptunium. The results of these studies will be used to evaluate the radiological hazard of specific radionuclides via the food chain to man.

PROGRESS: Report published on 241Am metabolism in dairy goats and cows. Preliminary data from 238/239Pu study indicated that the bioavailability of 239Pu is not much different from 238Pu, which was predicted from the differences in specific activity and non-biological solubility studies. Report: Cm transport in dairy animals - to GPO 3/79. Bioavailability of Cm similar to other actinides.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab. $298,000

DENVER STUDY

C.E. Rodes, U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab., *Research Triangle Park, North Carolina* 27711

OBJECTIVE: To obtain data in support of health effects study.

APPROACH: Equipment will be supplied, maintained, and calibrated at Jewish Children's hospital in Denver.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Environmental Monitoring & Systems Lab. $64,500

2.1253,

REYE'S SYNDROME AND TISSUE ORGANOCHLORIDES/OTHER CHEMICAL RESIDUES

R.G. Rowe, University of Minnesota, Duluth Campus, School of Medicine, Lake Superior Basin Studies Center, *2400 Oakland Ave., Duluth, Minnesota* 55812 (R805126-01)

OBJECTIVE: To determine if the disease Reye's Syndrome is correlated to bioaccumulated chemicals and to determine the body burden of selected chemicals in humans.

APPROACH: Tissues from persons dying from Reye's Syndrome are to be chemically analyzed and compared to persons dying by other causes. The analysis of the tissues is to be by GC-MS at the Duluth EPA laboratory.

PROGRESS. The available tissues have been amassed and the cases described. The tissues are now awaiting analysis at ERL-Duluth.

The grant portion of the project is completed and awaits in-house completion.

WATER QUALITY RESEARCH PROGRAM DEVELOPMENT

K.H. Mancy, University of Michigan, Ann Arbor Campus, Graduate School, Dept. of Environmental Chemistry, *Rackham Bldg., Ann Arbor, Michigan* 48104

OBJECTIVE: The PL480 research addresses the impacts of the Aswan High Dam on water quality in Lake Nasser and downstream portions of the Nile River. These water quality impacts are measured in terms of physical, chemical, and biological parameters. In human terms, impacts on agriculture, public health, and socioeconomic effects are also being examined. During 1975 and 1976, a country-wide water quality monitoring network along the River Nile and Lake Nasser was established. This network is supplemented by special functional surveys which include plankton, benthos, hydrophytes, and fisheries. The scientific information is being fed to an environmental information storage and retrieval system, called the Nile Data Bank. Public health impacts studies have been solely concerned with the effects of changes in water resources on parasitic diseases in rural Egypt. Agricultural impacts studies are based on laboratory and field assessment of the effects of changes in water quality with current and projected developments on Egyptian agricultural productivity. Socioeconomic impacts studies are concerned with the assessment of alternative development strategies on environmental effects useful to the decision maker.

PROGRESS: Scientific reports covering the various sub-project results were presented in the United States in September 1978 and a final report on the Public Health Sub-project was published as an EPA report in January 1979. Other final reports will follow. Project has been extended for an additional two years.

2.1257,

HEALTH IMPACTS OF ALTERED GEOCHEMISTRY ASSOCIATED WITH MINE DRAINAGE FROM WESTERN INTERIOR COALS

B.G. Wixson, University of Missouri, Rolla Campus, School of Engineering, Dept. of Civil Engineering, *Rolla, Missouri* 65401 (R807133)

OBJECTIVE: This study is designed to determine the existence of relationship between acid mine drainage contamination of potable water supplies and human health. This is to be done in the western interior coal region encompassing the states of Missouri, Iowa, Oklahoma, and Kansas.

APPROACH: The approach is through an ecologic study looking for relationships between epidemiologic data and water quality data. The epidemiologic data include county cancer mortality rates on 30 causes of death from NCI and census information. Water quality data include surface and ground water quality data and data obtained from samples of tap water.

RELATIONSHIP OF ORGANIC CONTAMINANTS IN DRINKING WATER TO CANCER MORTALITY AND MORBIDITY IN CONNECTICUT

R.S. Woodhull, State Dept. of Health, *79 Elm St., Hartford, Connecticut* 06115 (68-03-2775)

OBJECTIVE: This study will provide the necessary data on drinking water supplies in Connecticut to determine the relationship between (1) type of water supply and drinking water cancer and mortality over time and (2) organics in drinking water and the incidence of bladder cancer.

APPROACH: This objective will be accomplished through two studies: (1) Drinking water and cancer mortality - This study will utilize existing drinking water data for the state of Connecticut along with newly collected data for comparison with the tumor registry. (2) Bladder cancer study - This study is part of a large scale EPA bladder cancer study. It will be a case-control study using 540 cases and 1080 controls selected in Connecticut. Questionnaires will be given and water samples will be collected for chemical analysis.

2.1259,

RELATIONSHIP OF SODIUM AND OTHER INORGANIC CONSTITUENTS IN DRINKING WATER TO HYPERTENSION IN CONNECTICUT

A.V. Sardinas, State Dept. of Health, *79 Elm St., Hartford, Connecticut* 06115 (68-03-2699)

OBJECTIVE: An effort is being made to determine the amount of variability in sodium and other inorganic constituents found among water supplies in Connecticut. Once this variability has been ascertained it will be correlated with the occurrence of hypertension.

APPROACH: In addition to the compilation of historical water data, water samples will be collected from a random sample of households and analyzed for the various inorganic constituents. At the time of the water collection, the heads of households will be interviewed and screened for hypertension. The data will be analyzed to detect any relationships. From the hypertension screening survey, a population will be selected for a case-control study. The water samples of approximately 400 hypertensive individuals will be compared to water samples of approximately 400 matched normotensive individuals on the basis of the results of PIXE analysis.

PROGRESS: All interviews have been completed and all water samples have been collected. Analyses are underway. Selection of the 800 individuals for the case-control study is presently underway.

CASE-CONTROL STUDY OF WATER QUALITY AND CARCINOGENESIS IN PENNSYLVANIA

A.K. Bahn, University of Pennsylvania, School of Medicine, Dept. of Community Medicine, *36th & Hamilton Walk, Philadelphia, Pennsylvania* 19174 (R804594-01)

OBJECTIVES: One of the major aims of the project will be to devise and develop methods for evaluating possible links between colon cancer and substances in drinking water.

APPROACH: The investigation will be a 'case-control' study based on exposure histories of individuals. First, the water-drinking habits of persons who died from cancer of the colon will be compared with those of decedents whose cause of death was other than cancer; these subjects will be matched according to age, sex, and area of residence. Investigators will also seek information on lifetime occupation, diet, and smoking habits. At the same time, quality of water from a variety of sources, including surface and ground water supplies, will be examined. Any relationship between incidence of cancer of the colon and type, amount, or source of water consumed may then be discernible.

PROGRESS: The survey instruments have been developed and field tested. Arrangements have been made for obtaining names of decedent cases and controls from the State and more than one-half of the hospitals in the study area have agreed to participate in the study. Full-scale implementation of the study is currently underway.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab. $0

2.1261,

HUMAN HEALTH HAZARDS OF VIRUSES IN DRINKING AND RECREATIONAL WATERS

D.B. Nelson, University of Wisconsin, Madison Campus, Medical School, Dept. of Medicine/Preventive Medicine, *307 N. Charles St., Madison, Wisconsin* 53706 (R804161-03)

The basic objectives of the proposed study are: (1) to determine the minimum human oral infective dose of Sabin type 1 poliovirus strain in infants, (2) define the age specific rate of acquisition of antibodies to a number of important enteroviruses in young children with similar socioeconomic backgrounds who have different drinking water sources, (3) determine by serologic testing the incidence of enterovirus infections in children who participate in swimming classes at urban beaches and pools and compare to a control group engaged in non-swimming team sports, and (4) determine the frequency of recent exposure to recreational waters by children seeking medical attention with confirmed enteroviral illness and compare to a control group being seen for non-infectious problems. Data obtained from this study will indicate whether: (1) infants can be experimentally infected with very low oral doses of enterovirus, (2) children with similar socioeconomic backgrounds who are exposed to different types of drinking and recreational water sources acquire enterovirus infections at different rates, (3) children who swim frequently at beaches or pools acquire more infections than children who participate in non-swimming team sports, and (4) children with enteroviral illnesses have greater frequeny of swimming than children who did not acquire enteroviral illness during this time.

PROGRESS: The findings of this study showed that swimming children had a higher incidence of illness apparently of viral etiology than non-swimmers. Water contaminated by infected swimmers may have served as the transmission route, although definitive data were not obtained. Feeding studies with poliovaccine virus and 32 human infants indicated that about 70 times the dose required to infect 50% of the cell cultures (TCID50) was required to infect 50% of the infants; a dose of 50 TCID50 infected about 20% of the infants.

2.1262,

AN HISTORICAL COHORT EPIDEMIOLOGICAL STUDY OF THE HEALTH EFFECTS ON NEWBORNS AND INFANTS OF CLO2 AS A WATER DISINFECTANT

G.S. Moore, University of Massachusetts, Amherst Campus, School of Health Sciences, *Amherst, Massachusetts* 01002 (R806139-01)

OBJECTIVE: Chlorine dioxide is a powerful oxidant and chlorite, one of the by-products of ClO2 disinfection, is another powerful oxidant. The health effects of ClO2 disinfection of humans has not been fully assessed. There is evidence that pregnant mothers, fetuses in utero, and newborns may be at increased risk to oxidant stress and are likely to exhibit increased erythrocyte destruction and/or MetHb formation in blood cells exposed to chlorine dioxide or chlorite. The objective of this research is to assess the extent of this risk by an historical epidemiological study on these at risk groups in a population served by a water supply disinfected with ClO2.

Final draft report in preparation.

2.1263,

DISEASE TRANSMISSION ASSOCIATED WITH LAND APPLICATION OF WASTEWATER

H.I. Shuval, Hebrew University of Jerusalem, Hadassah Medical School, Environmental Health Lab, *P.O. Box 1172, Jerusalem 91000, Israel* (R806416-01)

OBJECTIVE: 1) To determine and measure if there is a degree of added risk of communicable disease incidence associated with wastewater land application and irrigation in agricultural communities (kibbutzim). 2) To determine the relationship between routes of transmission and disease incidence in the study population.

APPROACH: A prospective epidemiological study will be carried out in 30 kibbutzim in Israel which practice wastewater irrigation and in control groups not irrigating with wastewater. Health records of the various population groups will be studied and epidemiologic follow-ups of highly susceptible groups will be made (visiting volunteers, etc). Serologic and other lab tests will be used to compare infection rates of exposed and control groups. Air monitoring studies for aerosolized bacteria and viruses will be carried out.

2.1264,

DETECTION OF VIRAL GASTROENTERITIS AGENTS

N.R. Blacklow, University of Massachusetts, Medical School at Worcester, School of Medicine, Dept. of Medicine, *419 Belmont St., Worcester, Massachusetts* 01604 (R806591-01)

OBJECTIVE: The major objective of this project is to assess the contribution of viruses to environmentally transmitted enteritis.

APPROACH: The problem is being approached in two ways. The first approach is the development of new and more sensitive methods for the detection of agents in viral enteritis. This includes attempts to propagate the agents in vitro, and improvement of the sensitivity of immunological assays for these viruses that have already been developed in our laboratory. Development of new immuno-assays for viral agents of enteritis not previously studied is also planned. The second approach is to utilize techniques presently available in our laboratory for the study of naturally occurring disease outbreaks and for prospective seroepidemiological studies.

2.1265,

EPIDEMIOLOGICAL IMPACT OF GROUNDWATER RECHARGE

M. Nellor, Los Angeles County Sanitation District, *1955 Workman Mill Rd., P.O. Box 4998, Whittier, California* 90607 (R806399-01)

OBJECTIVE: To assess the potential health effects associated with the long-term use of drinking water which has been recharged in part with reclaimed water.

APPROACH: An epidemiology study will be done using existing data to determine if residents of an area which has been supplied with recycled water

differ in patterns of morbidity and mortality from residents in the same area prior to implementing recycling and from residents from similar communities drinking non-recharged water.

2.1266,

HEALTH EFFECTS OF HUMAN EXPOSURE TO BARIUM IN DRINKING WATER

B.W. Carnow, University of Illinois, Medical Center at Chicago, School of Public Health, Dept. of Occupational & Environmental Medicine, *Box 4348, Chicago, Illinois* 60680 (R803918)

OBJECTIVES: To determine by epidemiologic and supportive laboratory studies the health effects of consuming barium in Illinois drinking water exceeding the recommended drinking water standard of 1.0 mg/liter. Particular emphasis will be given to see if barium consumption is associated with cardiovascular and renal disease and the prevalence of hypertension.

APPROACH: (a) Mortality rates will be retrospectively examined for statistical differences between deaths attributed to cardiovascular diseases in communities in Illinois with elevated barium levels in their drinking water supplies and the National and State averages. Diseases examined will include hypertension, ischemic heart disease, peripheral vascular disease, cerebrovascular disease and renal disease. (b) A household morbidity study will be performed on an exposed population. Morbidity rates will be compared with the National and State averages. The exposed population will be subjected to blood pressure measurements and a questionnaire. Tap water samples from households will be analyzed for trace metal composition.

PROGRESS: We have identified those Illinois communities above the standard of 1.0 mg/liter. We have acquired Illinois State Death Certificate Tapes from which mortality rates will be examined. We have made initial contact with the communities involved in the morbidity study. Project completed with results showing an increase in death rates in population exposed to barium in their drinking water as opposed to those not exposed, and an increase in blood pressure for males exposed to 7.0 mg/l of barium in their drinking water when compared to similar population having less than 0.1 mg/l. Final report entitled; 'Health Effects of Human Exposure to Barium in Drinking Water' (EPA-600/1-79-003) published Jan. 1979.

2.1267,

A STUDY OF CANCER AND THE PUBLIC DRINKING WATER SUPPLIES IN MISSOURI

C.J. Marienfeld, University of Missouri, Columbia Campus, School of Medicine, Dept. of Community Health, *M228 Medical Sciences, Columbia, Missouri* 65201 (R805297-03)

Establishment and maintenance of a statewide surveillance system for human cancer incidence in relationship to the multiple sources of community public water supplies in Missouri and the methods of treatment of such local water supplies. Using the available mortality and morbidity data, a computerized rural route geocoding system will be used to locate the residence of the affected individuals identified as a part of the population at risk within the geographic water supplied area.

PROGRESS: Some interesting relationships have been observed in the cancer death rates in Missouri and water supply characteristics. Supplies have been classified as to impact of coal mining and burning. Results of the epidemiological studies seem promising and the studies will be continued. If more consistent relations are developed some more chemistry and bioassay would seem warranted.

EPIDEMIOLOGIC STUDY OF BLADDER CANCER RISK ASSOCIATED WITH TRIHALOMETHANES IN DRINKING WATER

K. Canter, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE: To assess the bladder cancer risks associated with exposure to purgeable organics in drinking water.

APPROACH: Include exposure to purgeable organics as one of the risk factors to be evaluated as part of the large National Cancer Institute supported study of bladder cancer and saccharine usage.

PROGRESS: All of the cases and controls have been interviewed, much of the historical water supply and water quality data has been abstracted, and the water sampling and analysis effort is well underway.

HEALTH CONSEQUENCES OF BENZENE CONTAMINATION OF DRINKING WATER

R. Miday, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE: A small population (35) of persons exposed to well water contaminated with benzene (8 ppm) will be studied to determine the incidence of adverse health effects.

APPROACH: Combined environmental, epidemiologic, and clinical pathological study utilizing an appropriate unexposed control group.

PROGRESS: Preliminary data analysis shows no association of biochemical abnormalities and benzene exposure.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab. $50,000

2.1275,

STUDY OF EFFECTS OF HOME WATER SOFTENERS ON BLOOD PRESSURES OF SCHOOL AGE CHILDREN - OHIO

A. Okun, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE: This project is designed to investigate the possible relationship between the sodium content of drinking water and increased arterial blood pressure. Based on past evidence, it appears that blood pressure should increase with sodium content when tested among groups of individuals. This proposal will investigate a source of sodium not previously examined and will hold water type constant. This will help to eliminate serious confounding variables not previously controlled.

APPROACH: A community having approximately 40% usage of home water softeners was surveyed. The blood pressures of the seventh grade students were taken and data was obtained on the necessary control variables. Water and urine samples were collected to verify water softener use. A 24 hour diet diary was also obtained to help control for other sources of sodium in the diet. Analyses are to be performed in order to test for blood pressure differences between water groups while controlling for confounding variables.

PROGRESS: All data collection has been completed. Water samples were obtained from all but 6 individuals having home water softeners. Water groups were confirmed for those individuals whose water sample sodium level differed from the expected value for their stated water group through telephone interviews. Data entry and cleaning is completed. An analysis strategy has been determined and analysis is presently progressing.

ASSESSMENT OF EFFECT (BODY BURDEN AND CARDIOVASCULAR) OF CHANGE IN BOSTON WATER SUPPLY

D. Greathouse, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE: To assess the effects of instituting corrosion control water treatment in an area that has lead and copper household plumbing materials.

APPROACH: Collect household water samples and toenail clippings from participants in a continuing V.A. health study before and 1 year after the initiation of corrosion control. Pre and past cardiovascular health will be determined by V.A. during the regular scheduled physical examinations. Effects will be compared among people exposed to a gradient of lead and copper in their drinking water.

PROGRESS: Tap water samples and toenail clippings were collected before and after the initiation of corrosion control treatment. The first stage water samples have been analyzed and analysis of the second stage samples is underway. Two hundred and thirty five participants provided samples before and after the change.

HEALTH EFFECTS OF ENERGY BYPRODUCTS ON DRINKING WATER

M.A. Shapiro, University of Pittsburgh, Graduate School of Public Health, Dept. of Industrial Environmental Health Sciences, *4200 5th Ave., Pittsburgh, Pennsylvania* 15260 (R805599)

OBJECTIVE: The objectives of this grant involve the determination of the health implications of contamination of drinking waters with by-products of coal mining and its use in the Eastern (Appalachian) coal mining region of the U.S. Immediate and future recommendations will be provided to the agency.

APPROACH: Sources of contamination (mining, coal conversion, etc) and composition of by-products will be identified. Methods of transport and pathways through which contaminants enter the drinking water will be determined. Using available toxicologic and epidemiologic liteature, the compounds likely to have a significant impact on the health of the exposed population(s) will be identified. Comparisons of morbidity and mortality rates for relevant diseases will be performed to signal any major public health problems.

PROGRESS: No results have been reported as of yet. A final report is expected by the end of the calendar year.

LEVELS OF CADMIUM-EXPOSURE INDICATORS IN THE UNITED STATES

D. Canavan, Swedish Hospital Medical Center, Laboratory of Pathology, *747 Summit Ave., Seattle, Washington* 98104 (CA8-3029-D)

There is a need to determine the prevalance of elevated beta2-microglobulin in the urine of persons in the United States. This low molecular weight protein is directly relaxed to the level of cadmium in the kidney. When the cadmium in the renal cortex reaches a certain concentration, proteinuria is initiated. Metabolism changes, especially with cadmium metabolism, are likely to occur even before the onset of proteinuria.

Studies by the Food and Drug Administration indicate that the cadmium intake through food and water in the United States is very close to the maximum intake recommended by the World Health Organization. With the factor of safety so small, it would be prudent to begin collecting data on whether or not a segment of the population is already showing signs of excess cadmium ingestion as evidenced by the buildup of beta2-microglobulin.

The proposed program is designed to obtain measurements of beta2-microglobulin, cadmium, specific gravity, and creatinine on 1000 different urine samples, which will be furnished by the Health and Nutrition Survey II of the National Center for Health Statistics. These data, together with other Survey results provided to us, will allow us to make preliminary evaluation of the health effects of cadmium in the United States, and to make a decision on whether to participate in the next Health and Nutrition Examination Survey (III, starting in 1980). Such participation would involve a major study on the levels of cadmium exposure in the U.S., and would require blood and feces, as well as urine, samples.

CAUSES OF DEATH OF ANESTHETISTS FROM THE CHLOROFORM ERA

H.W. Linde, Northwestern University, Chicago Campus, School of Medicine, Dept. of Anesthesia, *303 E. Chicago Ave., Chicago, Illinois* 60611 (R805473-01)

OBJECTIVE: To study the mortality of physicians who gave anesthesia during the period when chloroform was in common use, i.e. anesthetists dying prior to 1947.

APPROACH: Causes of death for anesthetists were obtained from American Medical Association records and from registrars of vital statistics. Causes of death were compared with those of the general population to determine if there were excesive deaths due to cancer.

PROGRESS: Results are available in EPA-600/1-79-043. It was found that combined death rates were lower among anesthesiologists than the U.S. male population, but exceeded them for some cardiovascular diseases. Death rates for combined malignant neoplasms were low, with digestive organ neoplasms being most common. Respiratory tract cancer was universally low.

A CASE CONTROL STUDY OF CHLORINATED DRINKING WATER AND CANCER

C.J. Lynch, Enviro Control Inc., *11300 Rockville Pike, 1 Central Plaza, Rockville, Maryland* 20852 (68-03-2727)

OBJECTIVE: The objective of this project is to determine if consuming chlorinated drinking water is a risk factor for the development of respiratory cancer in the presence of other known risk factors, such as smoking and occupational exposures.

APPROACH: This project is part of a large ongoing NCI case-control study of lung cancer and cigarette smoking that is managed by Enviro Control. Additional data being collected to answer the water chlorination question include water consumption data, residence history, occupational exposure history and water utility information. The relative risk associated with chlorinated drinking water exposure will then be determined after stratifying for tobacco consumption.

PROGRESS: Interviewing has been ongoing at all 6 study sites for three months. Collection of water utility data is underway.

CHROMOSOME STUDIES IN HUMAN SUBJECTS EXPOSED TO ARSENIC IN DRINKING WATER

B.K. Vig, University of Nevada, Reno Campus, School of Arts & Sciences, Dept. of Biology, *Reno, Nevada* 89507 (R805665-01)

The project is aimed at finding out if chromosome exposure of human population for 5 or more years to arsenic at concentrations of 0.05 mg/l or higher in drinking water increases the incidence of genetic damage measured as chromosomes aberrations and sister chromatid exchanges (SCE's) in comparison to those individuals who have been drinking water containing arsenic less than 0.01 mg/l, a limit recommended by the U.S.E.P.A. The plan calls for analyzing lymphocytes grown in vitro. Family histories about abnormalities of skin and other organs of the body shall be collected as well as the data on fetal wastage and abnormalities of births among the offspring of the couples who have been drinking arsenic-water. The studies shall be carried out in the area around Reno, Nevada, where a large number of families in rural areas depend upon the well water containing as high an amount of arsenic as mg/l.

2.1283,

A STUDY OF THE DISTRIBUTION AND HEALTH EFFECTS OF GIARDIA LAMBLIA IN DOMESTIC WATER SUPPLY

F. Frost, State Health Div., *Olympia, Washington* 98504 (R805809-02)

This proposal seeks support for continuation of a pilot research effort begun by the State of Washington. The efforts grew out of an outbreak of giardiasis in Camas, Washington in 1976. The proposal seeks to determine the distribution of Giardia lamblia in domestic water supply and whether health effects of Giardia contaminated water can be identified. The pilot project has been done in cooperation with Dr. Walt Jakubowski of HERL, Cincinnati. The proposal seeks to establish statewide case reporting system for laboratory confirmed Giardia infections using our pilot model of laboratory reporting and patient follow-up. It also seeks to continue use of commercial trappers to submit stool specimens from trapped water mammals. Thirdly, it will use an EPA developed filter for identifying Giardia contaminated surface water used as a source of drinking water.

PROGRESS: a widespread distribution of human cases of giardiasis has been revelaed in Washington State. Infected beaver and muskrat were found in 20 counties. Giardiasis occurs in many small outbreaks, among travelers, persons with backcountry exposures, children and in isolated cases with no obvious source.

2.1284,

STUDIES OF DRINKING WATER QUALITY AND CANCER IN IOWA

P. Isaacson, University of Iowa, School of Medicine, Dept. of Preventive Medicine & Environmental Health, *Jessup Hall, Iowa City, Iowa* 52240 (R806301-02)

OBJECTIVE: The basic objective is to use the extensive data and information resources of Iowa to further examine the human cancer risks associated with drinking water quality. In particular, the research effort will include assessments of the cancer risks associated with nitrates, radioactivity (radium 226), and energy related production by-products in drinking water.

APPROACH: Populations will be defined, or classified, into groups of similar exposure based on general or specific water quality factors. Within the defined groups, the population will be stratified by sex and community size. Actual and expected age adjusted cancer incidence rates will be computed for each subgroup. Incidence ratios (observed frequency/expected frequency) will be compared among comparable subgroups.

PROGRESS: Much of the available water quality data has been computerized; special purpose computer programs have been written; and preliminary assessments of cancer risks have been completed.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab. $221,000

2.1285,

HEALTH IMPACT STUDIES OF MINERAL FIBERS IN THE DULUTH MUNICIPAL WATER SUPPLY

L.J. Michienzi, State Dept. of Health, *717 Delaware St. S.E., Minneapolis, Minnesota* 55440 (R805428-01)

This research effort is to help evaluate the human health risk of prolonged exposures to mineral fibers.

The project will employ four different research methodologies to obtain information on the carcinogenicity of mineral fibers as found in the Duluth, Minnesota water supply prior to mineral fiber removal.

Two major classes of investigation will be undertaken: 1. A retrospective epidemiological evaluation of the incidence of cancers from all sites occurring within the target population: a. comparative analysis of age and sex; b. a case-by-case review of all cancers found within the population and evaluation of cancers by site relative to morbidity rates from the Third National Cancer Survey and the SEEK program of the N.C.I. These comparisons will be analyzed with consideration given to the environmental monitoring data compiled from the fourth part of the project (Environmental Surveillance). 2. The second overall method of risk assessment will be an in vitro study employing the so-called Ames screening method for determination of carcinogenicity followed up by use of mammalian cell cultures in an attempt to develop a dose-response relationship between the level of mineral fibers and degree of mutagenicity.

COMPARE OCCURRENCE AND LEVELS OF DRINKING WATER CONSTITUENTS AMONG 12 MATCHED PAIRS OF HIGH AND LOW CANCER MORTALITY COUNTIES (ABBREV)

D.G. Greathouse, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE: The aim of this project is to determine if matched counties with contrasting cancer mortality rates use drinking water that differs significantly in terms of occurrence and levels of contaminants, treatment technologies used, and/or source type (ground or surface).

APPROACH: Twelve pairs of matched counties were selected; matching criteria were region of the country, avg. educational level, percent of the population employed in the manufacturing industry, percent urbanization, total population years at risk. Within each pair, one county had a high and the other a low mortality rate for females due to colon, rectum, bladder, and liver cancer. Historical water quality and treatment information were collected for performance. Extensive water analyses were performed; analysis included determinations for 40 inorganics, trihalomethanes, TOC, fluorescence, asbestos, radionuclides, and mutagens.

PROGRESS: The field work has been completed and all water samples have been analyzed. Most of the data has been computerized. It is anticipated that the data analysis effort will begin by October 1, 1979 and be completed by March 31, 1980.

EPIDEMIOLOGICAL STUDY BY ASBESTOS EXPOSURE IN CONNECTICUT

G.F. Craun, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Epidemiology Branch, *Research Triangle Park, North Carolina* 27711

The age adjusted sex specific incidence data for stomach, colon, and rectal cancer for Connecticut townships for the period 1935 to 1973 were used to investigate whether asbestos cement pipe usage for transporting domestic drinking water is associated with gastrointestinal cancer. The townships were grouped according to the assessment of exposure (AOE) and risk factor (RF) for asbestos. These are composite indices of asbestos exposure including factors relating to the age of the pipe, the ability of water to leach asbestos from the pipe, and the length of pipes used by the population. No association was noticed between these asbestos risk scores and gastrointestinal tumor incidence.

Results of study utilizing actual fiber count data from the Connecticut water supplies and a more sophisticated analysis procedure did not show any association. A paper describing the study has been submitted to the Envir. Health Journal.

STUDY OF THE HEALTH EFFECTS OF SODIUM IN DRINKING WATER

R.W. Tuthill, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Field Studies Div., Epidemiology Branch, *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVES: To replicate, under identical circumstances, a recent study reported from University of Massachusetts, Amherst. In that study the distribution of blood pressure of school children in a high sodium community (106 ppm) was significantly upshifted when compared to the children of a low sodium community (8 ppm). The current study will compare two communities with 22 and 376 ppm sodium respectively to replicate the earlier findings and to ascertain a possible dose response as a basis for a sodium drinking water standard.

APPROACH: The blood pressure of 7th grade pupils will be taken by carefully standardized individuals in the schools of both communities. A 24 hour dietary diary, home water samples, and first morning urine samples will be obtained on a sub-set of approximately 100 children in each community and analyzed for sodium and potassium. Report is being written.

DEVELOP AND EVALUATE METHODS FOR ISOLATION AND IDENTIFICATION OF GASTROENTERITIS BACTERIA FROM ENVIRONMENTAL AND CLINICAL SAMPLES

T.H. Ericksen, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVES: To develop selective and differential methods for the isolation, detection, enumeration and identification of pathogenic bacteria associated with outbreaks and endemic gastroenteritis.

APPROACH: Laboratory experiments involving modification of temperature, pH, concentration technics, nutrient type and level will be performed. Specific agents to be investigated initially will be Campylobacter, Yersinia and enterotoxigenic E. coli.

PROGRESS: Draft protocols for isolation and detection of Salmonella, Shigella, Campylobacter, yersinia and enterotoxigenic E. coli from water samples have been prepared. The protocols are undergoing review

and will be used as a basis for studies under this task.

ASSESSMENT OF ASBESTOS EXPOSURE TO U.S. PUBLIC FROM DRINKING WATER

J.R. Millette, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

Over 1500 asbestos analyses of water supplies in 43 states, Puerto Rico and the District of Columbia were evaluated in order to assess the exposure of the United States Population to asbestos in drinking water. It was concluded that the large majority of U.S. water consumers are not exposed to concentrations of asbestos fibers above one million fibers per liter. In a few areas people are exposed to concentrations up to one hundred million fibers per liter. The majority of persons receiving water from asbestos-cement pipe distribution systems are not exposed to significant number of fibers from the pipe. In areas of aggressive water, however, water consumers using asbestos-cement mains may be exposed to high concentrations of fibers.

2.1297,

AN ENVIRONMENTAL HEALTH STUDY OF LEAD IN TEETH

D.R. Wilkinson, Delaware State College, Undergraduate School, Dept. of Chemistry, *Dover, Delaware* 19901 (R802890-03)

The proposed research program is designed to determine lead concentration in deciduous teeth of children under age 6, as well as in contaminating dust samples from the homes of the donors and air samples from the immediate area. In addition, automobile traffic rates in the immediate area will be studied and socioeconomic data collected on the families of children under study. The teeth samples will be collected in Birmingham, England, a city which offers a unique laboratory for such a study, i.e. a tremendously large traffic cloverleaf, around which are constructed many high-rise apartments, and a state housing development. In addition England offers a state health program offering personal information on donors and their families. Samples of teeth will be collected in England, coded, and mailed along with data to Delaware State College where they will be freeze-ground, put into solution and volumetrically brought up to a predetermined volume. The concentration of lead will be determined through the use of a Jarrel-Ash 810 Atomic Absorption Spectrophotometer. The results will add to knowledge presently being obtained concerning the ability to determine lead accumulated in the body by a technique which will cause little or no damage to the donor. The correlation between automobile traffic, lead accumulation levels and morbidity patterns should be shown.

PROGRESS: A draft narrative report has been received from the grantee. It is under review, with initial comments suggesting the significant refinement will be needed.

EVALUATION OF THE HEALTH RISKS ASSOCIATED WITH THE TREATMENT AND DISPOSAL OF MUNICIPAL WASTEWATER AND SLUDGE

C.S. Clark, University of Cincinnati, School of Medicine, Dept. of Environmental Health, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221 (R805445-01)

This three part study is intended to be the first phase of a long-term effort to prepare guidelines to minimize the health effects from the land application of municipal wastewater and sludges and from other treatment processes. Population groups to be considered are those occupationally exposed to all aspects of the waste-handling operations, those exposed by way of their living, working or having recreational pursuits nearby and those who consume or otherwise come into contact with any crops or other products of the treatment system. The first part consists of an evaluation of current information on the health risks utilizing existing reviews and assessments as well as supplemental literature search. This evaluation will also result in detailed plans for additional studies that are needed.

A pilot study of workers exposed to heat dried municipal sewage sludge that is ultimately applied to the land comprises the second part of the project. Included in the pilot study is a determination of the chemical and biological properties of the sludge and examination of the workers for possible effects of the sludge constituents.

The third part is a cause of death study of former employees of a large wastewater treatment system to determine if any causes of death occur more frequently than expected. The results of this mortality study will be used to help define the need for additional research.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab. $559,300

EPIDEMIOLOGICAL STUDY OF WOMEN EXPOSED TO STYRENE AND REPRODUCTIVE DYSFUNCTION

G. Lemasters, University of Cincinnati, School of Medicine, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221 (R806669-01)

OBJECTIVE: The objectives are to determine whether or not women occupationally exposed to styrene experience any reproductive dysfunction when compared with a similar working unexposed control group, and to determing if measuring reproductive dysfunction is a useful methodology for monitoring populations exposed to toxic chemicals.

APPROACH: The approach is through the use of an historical cohort epidemiological study of women aged 18-30 who have worked in the styrene manufacturing industry. A questionnaire will be administered via telephone to the exposed and unexposed workers to measure spontaneous abortion, menstrual dysfunction, stillbirth, prematurity, infertility and congenital malformation.

STUDY OF BLOOD LEAD LEVELS IN URBAN AND REMOTE POPULATIONS

S. Piomelli, New York University, School of Medicine, Dept. of Medicine, *550 1st Ave., New York, New York* 10016 (DA8-1686-J)

OBJECTIVES/APPROACH: To establish a natural background level of lead in blood. A population of Nepolese natives and New York City residents will be tested for air lead exposures/blood lead levels/HB/EP/and ferritin.

PROGRESS: Due to very low blood leads being observed, further quality control efforts are being made before majority of samples are being analyzed. Delays in submission of final report are inevitable.

LEVELS OF CADMIUM-EXPOSURE INDICATORS IN THE UNITED STATES

H. Barbano, U.S. Dept. of Health & Human Services, Public Health Service, Office of Health Research Statistics & Technology, National Center for Health Statistics, Methodology & Plans Section, *3700 East West Hwy., Hyattsville, Maryland* 20782 (D8-F0270)

There is a need to determine the prevalence of elevated beta2-microglobulin in the urine of persons in the United States. This low molecular weight protein is directly related to the level of cadmium in the kidney. When the cadmium in the renal cortex reaches a certain concentration, proteinuria is initiated. Metabolism changes, especially with calcium metabolism, are likely to occur even before the onset of proteinuria. Studies by the Food and Drug Administration indicate that the cadmium intake through food and water in the United States is very close to the maximum intake recommended by the World Health Organization. With the factor of safety so small, it would be prudent to begin collecting data on whether or not a segment of the population is already showing signs of excess cadmium ingestion as evidenced by the buildup of beta2-microglobulin. The proposed program is designed to obtain measurements of beta2-microglobulin, cadmium, specific gravity, and creatinine on 1000 different urine samples, which will be furnished by the Health and Nutrition Survey II of the National Center for Health Statistics. These data, together with other Survey results provided to us, will allow us to make preliminary evaluation of the health effects of cadmium in the United States, and to make a decision on whether to participate in the next Health and Nutrition Examination Survey (III, starting in 1980). Such participation would involve a major study on the levels of cadmium exposure in the U.S., and would require blood and feces, as well as urine, samples.

INVESTIGATION OF WATERBORNE DISEASE OUTBREAKS

E.C. Lippy, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., *5555 Ridge Ave., Cincinnati, Ohio* 45268

Isolate causative agent of outbreak from water system, determine route of entry, propose corrections to prevent reoccurrence.

Collection of samples using large volume sampling techniques and laboratory analysis to identify causative agent. Engineering evaluation of water system to determine how, when and where contaminant entered the system and recommend corrective measures to prevent future occurrence.

Investigate 4-6 waterborne outbreaks annually. Continue to improve techniques and methodology so agent isolation is improved from current 50% detection rate. Publicize deficiencies in water systems to reduce number of waterborne outbreaks.

INORGANIC ANALYSES TO SUPPORT EPIDEMIOLOGIC STUDIES

K. Kelty, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Field Studies Div., Water Analysis Group, *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE/APPROACH: To provide inorganic analyses for epidemiological studies. Samples of drinking water are being analyzed for a variety of parameters, including pH, conductivity, hardness, alkalinity, flu-

oride, nitrates, Na, Mg, Li, Be, Si, Pb, Cd, Cu, Zn, and Fe.

OUTPUTS: Analysis of 1,000 Boston drinking water samples (4,092 elemental determinations). Analysis of 630 Boston tissue samples (2,520 elemental determinations).

SIGNIFICANT RESULTS: A new method for the determination of Pb and Cd has been evaluated and successfully applied. It consists of a modification of Middleton's digestion procedure (Analyst: 79, p. 138-147) and an adaptation of Henn's atomic absorption method (ASTM STP, pp 54-64).

PROGRESS: Approximately 3600 analyses of drinking water for the cancer studies were completed and reported on December 8, 1978. Currently drinking water samples exposed to asbestos piping are being analyzed.

ENUMERATION METHODS FOR HEALTH EFFECTS WATER QUALITY INDICATORS

A.P. Dufour, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Marine Field Station, *Liberty Ln., West Kingston, Rhode Island* 02892

The objective is to evaluate existing or develop new methods for the enumeration of microbial pathogens and indicators potentially important in the development of health effects criteria for marine and fresh recreational waters. These indicators are evaluated in the course of epidemiological studies and examined for their applicability in the characterization of pollution sources.

Methods will be developed for coliforms and coliform biotypes including E. coli and Klebsiella, enterococci and enterococcus biotypes. P. aeruginosa, C. perfringens, chlorine resistant coliphage; A. hydrophila bifidobacteria, salmonellae and enteropathogenic E. coli. Extramural resources are being used to develop methods for C. albicans, Yersinia enterocolitica, Shigella and E. coli of human origin. Emphasis is on membrane filter methods because they tend to be precise and facile and amenable to the examination of large quantities of water.

Methods have been developed and evaluated for nearly all of the fecal and environmental indicators. Methods development for most of the pathogens is in progress.

PROGRESS: Report for criteria document being written.

SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab. $68,000

ANNUAL REVIEW OF WATERBORNE DISEASE OUTBREAKS

G.F. Craun, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Epidemiology Branch, *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVES: Disseminate information on Waterborne Outbreaks to the Scientific, Regulatory and Political Community.

APPROACH: A worldwide literature review is conducted annually and data on waterborne outbreaks are summarized. Detailed analyses of drinking water related outbreaks in the U.S. are compiled annually in cooperation with the CDC and State regulatory agencies.

PROGRESS: Latest literature review, June 1978, published in Journal Water Pollution Control Federation. Update on drinking water related outbreaks presented at the Annual Conference of the American Water Works Association in June 1978. Reports appear in JAWWA (71:422-428, 1979), AJPH (69:817-819, 1979) and journal at Env. Hlt. (41:259-265, 1979). The annual review of waterborne outbreaks has been submitted to JWPCF for the June 1980 issue.

SCREEN SERA FROM AEROSOL EPIDEMIOLOGICAL STUDIES FOR ANTIBODY TO LEGIONNAIRES' DISEASE BACTERIUM

T.H. Ericksen, U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Field Studies Div., Epidemiology Branch, *5555 Ridge Ave., Cincinnati, Ohio* 45268

OBJECTIVE: To determine if sewage and/or its treatment is a possible route of exposure for persons to Legionnaires' Disease Bacteria (Legionella pneumophila).

APPROACH: Sera already obtained from sewer workers and persons living in the neighborhood of sewage plants, will be tested for antibodies to LDB using the IFA method developed by Center for Disease Control, Atlanta, Georgia. These results will be compared to those obtained from the sera of control groups. The results obtained from this study could determine the role of sewage as a possible source of LDB in the environment, thereby contributing to its spread and exposure to susceptible populations.

PROGRESS: Training of personnel in the methodology to be used is complete. Arrangement for transfer of the necessary equipment under revocable license is in progress. Some of the reagents necessary for testing have been obtained from Center for Disease Control.

PUBLISH PROCEEDINGS OF NATIONAL SYMPOSIUM ON WATERBORNE TRANSMISSION OF GIARDIASIS

J.C. Hoff, U.S. Environmental Protection Agency, Office of Research & Development, Municipal Environmental Research Lab., Water Supply Research Div., *26 W. St. Clair St., Cincinnati, Ohio* 45268

OBJECTIVE: The objective of this task is to combine 19 manuscripts, 7 abstracts, open discussions, and a panel discussion from a jointly sponsored HERL-MERL symposium held in September 1978 into a state-of-the-art document on waterborne transmission of giardiasis.

APPROACH: Private contractors will be utilized to typemark manuscript material, typeset the document, and do initial proofreading. Paste-up will be done in-house. Approximately 5000 copies of the final document will be printed.

PROGRESS: Typemarking, typesetting, and initial proofreading have been completed. Recipients of copies are being identified and approximately 4,000 requests have been received for copies.

This task completed June, 1979 with issuance of publication No. EPA-600/9-79-001, 'Waterborne Transmission of Giardiasis.'

IDENTIFICATION AND PREVALENCE OF YERSINIA ENTEROCOLITICA IN WASHINGTON STATE WATER SUPPLIES

T.F. Wetzler, University of Washington, School of Public Health & Community Medicine, Dept. of Environmental Health, *4000 15th Ave. N.E., Seattle, Washington* 98105 (R805313-02)

OBJECTIVE: Determine prevalence of Yersinia enterocolitica and indicator organisms in non-treated, filtered and chlorinated water supplies in Washington State. Identify the isolates and determine their virulence. Produce antisera to non-typable strains isolated. Establish levels of yersiniosis in Washington State and attempt to establish the source of the etiologic agent.

APPROACH: Examine water samples from 50 selected water systems. Indicators of the sanitary quality of the water are also determined. All Yersinia isolates will be identified biochemically and serologically. Antisera developed for untypable strains will be developed. Virulence testing of Yersinia isolated includes the 'suckling' mouse test and gerbil yersiniosis will be correlated to potential water-or food-borne transmission.

PROGRESS: Biochemical properties, biochemical profiles and serologic typing have been completed on approximately 154 Yersinia isolates obtained from 57 water utilities in Washington State. Antisera for 25 European strains has been prepared. Antisera for untypable strains is in progress. Virulence testing with 'suckling' mice and gerbils has been standardized.

DEMONSTRATION PROGRAM TO SHOW OHIO LANDOWNERS AND MUNICIPALITIES ACCEPTABLE SYSTEMS FOR APPLYING SLUDGE ON LAND

V.V. Hamparian, Ohio State University, Columbus Campus, School of Medicine, Dept. of Medical Microbiology, *370 W. 9th Ave., Columbus, Ohio* 43212 (S805189-01)

OBJECTIVE: Health effects in humans and animals resulting from the application of municipal sewage sludge to farms in Ohio will be evaluated. Subjects covered include: (1) Monitoring of pathogens in stools, sludge, and soil. (2) Monitoring farm family health status and serology. (3) Relating sludge virus to viral infections. (4) Investigating viability of soil pathogens. (5) Monitoring health status of farm animals. (6) Monitor trace element accumulation of cattle. (7) Measure parasite survival and infection rate of cattle. (8) Monitor animals for tuberculosis and Salmonella infection. 9. Monitor cadmium content in stools and relate to cadmium intake.

A LONGITUDINAL EVALUATION OF LEAD BODY BURDEN IN GROWING CHILDREN

A.H. Lubin, Childrens Hospital, *561 S. 17th St., Livingston Pike, Columbus, Ohio* 43205 (R804168-03)

OBJECTIVE: The objective of this study is to assess the association of biochemical nutritional and growth parameters with the amount of exposure of commonly accepted sources of environmental lead (air, dust and water) during the mother's pregnancy and in the offspring's subsequent first two years of life.

APPROACH: Approximately 200 children in each of three cities, Columbus, Ohio; Boston, Massachusetts; and New Bedford, Massachusetts are being enrolled and prospectively followed during the first two years of life, with frequent personal and environmental sampling.

PROGRESS: Initial data indicate a correlation between lead in blood of the mother, cord blood lead, and newborn infant lead values. Lead in dust results confirm dust to be a significant source of lead intake.

CROSS-SPECIES TRANSMISSION OF GIARDIA

C.P. Hibler, Colorado State University, College of Veterinary Medicine & Biomedical Sciences, Dept. of Pathology, *Fort Collins, Colorado* 80523 (R805215)

OBJECTIVE: Determine if it is possible for various wild and domestic animals to act as reservoirs for human Giardia in the environment.

APPROACH: Live-trapped wild animals and various domestic animals were examined for Giardia. Negative animals were exposed to human Giardia and their feces examined for Giardia. Giardia present in animals upon initial examination were given to SPF dogs which acted as human surrogates.

PROGRESS: Animals, such as beaver, muskrat, mountain sheep, dogs, and cats, can serve as Giardia carriers in the environment. Infected animals could, therefore, disseminate Giardia into water used for drinking. Draft final report submitted for review.

AN EPIDEMIOLOGICAL STUDY OF PRESQUE ISLAND STATE PARK BEACHES ON LAKE ERIE, ERIE, PENNSYLVANIA

S.J. Zagorski, Gannon College, Undergraduate School, Dept. of Biology, *109 W. 6th, Erie, Pennsylvania* 16501 (R806791-01)
OBJECTIVE: The objective of this proposal is to correlate the incidence of illness among bathers with the quality of water as indicated by results of bacteriological assays obtained from fresh recreational water sites on Lake Erie, Erie, Pennsylvania. The sites selected are expected to differ substantially in water quality, one known to be impacted by contamination and the other relatively clean. Computer assisted analysis of the data will employ a SAS program already developed.
APPROACH: Conduct bacteriological and epidemiological surveys at the beaches and by telephone follow-ups. Microbial assays include those for Escherichia coli, Clostridium perfringens, and enterococci. Results of these studies should amplify the development of fresh recreational water quality criteria.
PROGRESS: Bacteriological surveys pinpoint the source of contamination impacting one of the test beach areas and show no impact on the other site selected. All assay procedures, survey forms, and statistical analyses procedures to be employed have been used successfully in other research programs.
Final report being written.

THE DEVELOPMENT OF CRITERIA FOR RECREATIONAL WATERS

J.L. Gale, University of Washington, School of Public Health & Community Medicine, Dept. of Epidemiology & International Health, *4000 15th Ave. N.E., Seattle, Washington* 98105 (R806841-01)
OBJECTIVE: The project's objective is to provide information for the development of fresh recreational water quality criteria by obtaining data on the level of contamination in the water and relating these to data obtained on human health effects.
APPROACH: Conduct bacteriological and epidemiological surveys at two beaches on Lake Washington near Seattle, conduct telephone follow-ups, and statistically determine the relationship between microbial indicator densities in the water and illness among exposed bathers. Microbial assays include those for Escherichia coli, enterococci, and Clostridium perfringens.
PROGRESS: Results of bacteriological assays distinguish two beaches on Lake Washington, one heavily impacted by contamination, the other with no significant fecal pollution. These are the identified test and control beaches in this proposal. All assay procedures, survey forms, and statistical analyses procedures to be employed in this study have been used successfully in other research programs.
Final report being published.
SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Health Effects Research Lab., Marine Field Station $37,000

2.1330,

DEVELOPMENT OF CRITERIA FOR FRESH RECREATIONAL WATERS

J.M. Robertson, University of Oklahoma, Norman Campus, Office of Research Admin., *1000 Asp Ave., Room 314, Norman, Oklahoma* 73069 (R806712-01)
OBJECTIVE: The objective of this proposal is to correlate the incidence of illness among bathers with the quality of water as indicated by results of bacteriological assays obtained from fresh recreational water sites near Tulsa, Oklahoma. The sites selected are expected to differ substantially in water quality, one being impacted by a known source of contamination and the other relatively clean. Computer assisted analysis of the data will employ a SAS program already developed.
APPROACH: Conduct bacteriological and epidemiological surveys at the beaches and by telephone follow-ups. Microbial assays include those for Escherichia coli, Clostridium perfringens, and enterococci. Results of these studies should amplify the development of fresh recreational water quality criteria.
PROGRESS: Bacteriological surveys pinpoint the source of contamination impacting one of the test beach areas and show no impact on the other site selected. All assay procedures, survey forms, and statistical analyses procedures to be employed have been used successfully in other research programs.

METHODOLOGIES FOR UTILIZATION OF ENVIRONMENTAL-IMPACT-ASSESSMENT DATA

L.R. Babcock, University of Illinois, Chicago Circle Campus, School of Engineering, *Box 4348, Chicago, Illinois* 60680 (R805476)
OBJECTIVE: To define methodological approaches for use within the EPA which would facilitate the identification of hazards and setting of standards and control priorities.
APPROACH: Define methodology of use by health-effects personnel and others of environmental impact and assessment data to generate meaningful cause-effect results.
SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Industrial Environmental Research Lab. $71,000

2.1332,

DEMONSTRATION PROGRAM TO SHOW LANDOWNERS AND MUNICIPALITIES ACCEPTABLE SYSTEMS FOR APPLYING SLUDGE ON LAND

J.K. Hill, Farm Bureau Development Corp., *245 N. High St., Columbus, Ohio* 43216 (S805189-01)
OBJECTIVE: The objective is to demonstrate safe, beneficial use of wastewater sludge as a soil amendment on agricultural land. Institutional arrangements to permit objective evaluations and decisions by both rural and urban residents will be demonstrated. The effect of proper application and management of a land application of sludge on public health and the environment will be determined.
APPROACH: Four communities in Ohio that already dispose of sludge by spreading it on farm land will supply sludge for application to selected farms in a carefully planned and managed system. In addition to sludge application on fields, sludge will be applied to carefully selected plots for measurement of its effect on yield and composition of crop, composition of soil, and consumption of ground and surface water. An epidemiological study of livestock and people who come in contact with sludges will measure the health effects of sludge spreading.
SUPPORTED BY U.S. Environmental Protection Agency, Office of Research & Development, Municipal Environmental Research Lab. $450,000

2.1333,

IDENTIFICATION AND EVALUATION OF WATERBORNE EXPOSURE ROUTES TO HUMANS FROM OTHER THAN FOOD AND DRINKING WATER

A. Wechsler, Arthur D. Little Inc., *15 Acorn Park, Cambridge, Massachusetts* 02140 (68-01-3857)
OBJECTIVE: To develop and test a framework/methodology for identifying and evaluating the populations exposed and risks associated with routes of exposure to waterborne priority pollutants other than by food and drinking water ingestion.
APPROACH: (1) Identification of routes of exposure, exposure activities, extent and frequency of exposure, and subpopulations exposed; (2) development of criteria for evaluation of the potential significance of exposure via alternate waterborne routes.
CURRENT PROGRESS: Potential exposure routes have been identified, and classified according to type of activity, type of water associated with the exposure route, and other descriptive categories, e.g., frequency and extent of exposure, geographic and population factors. literature search was done to determine kinds and availability of data to fit categorization scheme. Task complete. Report will be available in early 1979.
SUPPORTED BY U.S. Environmental Protection Agency, Office of Water & Waste Management, Office of Water Planning & Standards $0

2.1334,

DEVELOPMENT AND TESTING OF ASSESSMENT METHODOLOGIES APPLIED TO THE GENETIC AND CHRONIC FUNCTIONAL IMPAIRMENT IN HUMANS

A.E. Wechsler, Arthur D. Little Inc., *15 Acorn Park, Cambridge, Massachusetts* 02140 (68-01-3857)
OBJECTIVE: To review, evaluate and develop risk assessment metholodogies for genetic and chronic (non-carcinogenic) functional impairments, followed by application of these methodologies in two risk assessments. To refine and integrate risk assessment methodology.
APPROACH: (1) To perform a literature review of methods currently used to extrapolate experimental data to yield possible known effects for mutagenicity, teratogenic and chronic functional impairments, (2) Develop assessment methods for genetic and chronic functional risk catagories for carcinogenic risks in humans, (3) To propose an integrated risk assessment using materials balance, environmental fate and monitoring data to assess exposure to human and nonhuman. The methodology will then be tested on zinc and phthalate esters. This will be used to determine ranges of human risks associated with carcinogenicity, genetic, and functional disorders.
SUPPORTED BY U.S. Environmental Protection Agency, Office of Water & Waste Management, Office of Water Planning & Standards $0

DEVELOPMENT AND OPERATION OF A STATEWIDE FIRE INCIDENT AND CASUALTY REPORTING SYSTEM

R.W. Mafley, State Div. of Fire Prevention, *1010 Commonwealth Ave., Boston, Massachusetts* 02215 (U.S.F.A.-79010)
OBJECTIVE: Develop, implement, and operate a comprehensive statewide uniform fire incident and casualty reporting system. Initiate a computerized data collection and retrieval system at the State level encompassing fire and police arson investigation reports, laboratory reports, and insurance adjustment reports filed within the State Fire Marshal's office.
APPROACH: The collection of data from cities and towns will be aggregated and tabulated and will be distributed by the State Fire Marshal.
CURRENT PLANS: The primary consideration is to train full-time, part-time and volunteer fire departments in the proper procedure of coding the 902F form.
PROGRESS: Orientation by National Fire Data Center Scheduled Instructors Class, April 23, 24, 25, 1979, in the NFIRS program.
SUPPORTED BY U.S. Federal Emergency Management Agency, U.S. Fire Admin. $20,000

A STUDY OF RESPIRATORY VIRUS TRANSMISSION AMONG PERSONNEL IN ISOLATION IN ANTARCTICA

E.C. Dick, University of Wisconsin, Madison Campus, Medical School, Dept. of Preventive Medicine, *307 N. Charles St., Madison, Wisconsin* 53706 (DPP76-83918 A01)

The University of Wisconsin proposes an investigation of person-to-person transmission of common cold viruses in an isolated population of 200 at McMurdo Station, Antarctica. This population is unique in that it consists of normal American citizens (primarily United States Naval personnel) with their normal complement of colds who will suddenly be completely isolated for about 5 weeks. It should be possible during this period to follow the movement of common cold viruses through this population without 'outside viruses' entering the chain of infection. Careful study of the characteristics of each person's illness and the inter-personnel methods by which person-to-person transmission can be interrupted. This approach seems promising, as prior studies in open populations and in human volunteers suggest that colds may be more difficult to transmit than previously supposed.

Analysis of data detained during the 77/78 field season will be carried out at the University of Wisconsin, Madison.

This research represents a continuation of that currently supported by DPP-7683918.

EFFECTS OF INDUSTRIALIZATION ON MORTALITY RATES

T. Hershberg, University of Pennsylvania, Graduate School, *203 Logan Hall, Philadelphia, Pennsylvania* 19104 (SES79-07128)

This project provides an empirical evaluation of competing theories explaining differing reductions in mortality for various socioeconomic sectors of a modernizing urban population. At issue is the effect on mortality of the availability of health care, sanitation, and diet and housing improvements for different social groups. Specific questions focus (a) on patterns of age, sex, and cause-of-death mortality by racial, ethnic, and occupational groups, with a special emphasis on the experience of urban blacks; and (b) on the effects on changes in these group-specific patterns attributable to access to water and sewer facilities, population densities, proximity to industrial pollutants, health care, and housing characteristics and composition. To be illustrative of major modernizing trends generally, the study focuses on changes in a developing American city, Philadelphia, during a period of rapid socioeconomic advance, the late nineteenth century. The relevant Philadelphia data, while unique in detail and quality pertinent to the central issues, also contain sufficiently large numbers of blacks and immigrant populations to permit comparison of the differing impact of early industrial development on their individual survival rates. The study will develop new techniques of mortality analysis for spatially separated groups and will provide inferences having current applications elsewhere.

SOCIOECONOMIC DETERMINANTS OF CHANGES IN MORTALITY RATES

A. Palloni, University of Texas, Austin Campus, School of Social & Behavioral Sciences, Dept. of Sociology, *200 W. 21st, Austin, Texas* 78712 (SOC79-08288)

Latin America has experienced long-term increases in life expectancy and decreases in mortality rates that exceed the change rates for the transition period in Europe. Yet, recent signs indicate a slowdown in change rates for Latin America that may still keep the continent below the pace-setting standards of Europe. This research seeks to provide a more detailed specification of the Latin American change rates and an explanation for them over the last seventy years. Among factors affecting mortality decline, the study considers the impact of endogenous developments (i.e., rising standard of living) and exogenous developments (introduction of new and low-cost medical technology). The study will trace the separate and joint effects of these developments on overall mortality and on changing variation in the causes and rates of mortality by levels of socioeconomic status. The research employs available documentary data from death registrations, population censuses, and other records. This research should help extend basic knowledge of empirical regularities in trends and causes of human death, leading to the day when general theories of mortality change can be more confidently advanced.

THE SIMULATION OF INFLUENZA DIFFUSION

G.F. Pyle, University of Akron, Center for Urban Studies, *302 E. Buchtel Ave., Akron, Ohio* 44304 (SOC79-05530)

From past experience it is known that the spread of a new strain of influenza virus throughout the country into a nonimmune population can have serious consequences. While a number of hypotheses exist that help to explain the spread, little is known of the actual process by which an influenza virus diffuses throughout geographic space. In part, this is because the origin locations of viruses tend to differ with different strains. In part also, it is because geographic changes occur from one time to another in the factors involved in the diffusion process: population size, travel patterns and transport infrastructure linkages, for example. The purpose of this research is to modify and apply current methodologies used to describe and explain the temporal-spatial diffusion of other phenomena to simulate the spread of influenza. Such methods take into account various propositions hypothesized to be associated with the spread of diseases and include simulation techniques employed in hierarchical, linear and radial diffusion processes.

The research will perform several simulation experiments using different hypothesized variables to replicate the 1946 and 1957 influenza diffusion patterns. The relationships between each simulated pattern will be statistically tested against the actual pattern for specific penetration periods of the influenza season. Using the results of this research, the 1968 pattern will be simulated and the relationship to the actual pattern tested statistically.

The knowledge obtained from the research can be used to simulate the spread of new influenza viruses for which barriers can be created to hinder its progress. The knowledge would be applicable to other disease agents known to diffuse in a geographic fashion.

ECONOMIC MODELS OF THE DETERMINANTS OF CHILD HEALTH

M.R. Rosenzweig, Yale University, Graduate School, Dept. of Economics, *206 Elm, New Haven, Connecticut* 06520 (SOC7814481)

This research develops and tests economic models of the determinants of child health and mortality using cross-sectional individual survey data in combination with local community information. Empirical analyses are planned based on U.S., rural Indian and Colombian representative household samples, with the objective of evaluating the impact of individual characteristics, environmental conditions, and medical services on indicators of infant health. Such indicators include the probability of survival and biometric transformations of birthweight. In addition to estimating reduced-form equations, more restricted models are explored in which related family behavior such as mother's labor supply, duration of breast feeding, and the demand for consumption and medical inputs are treated as jointly determined and the relevant structural equations estimated. Regional information on prices and on labor market variables, which can be considered exogenous to individual household health outcomes and health-related activities, aid in the identification of these structural equations.

ENVIRONMENTAL RISK FACTORS IN NASOPHARYNGEAL CARCINOMA IN MALAYSIA

R.W. Armstrong, University of Hawaii System, Manoa Campus, School of Arts & Sciences, Dept. of Geography, *2444 Dole St., Honolulu, Hawaii* 96822 (SOC79-10521)

The objective of this research is to compare the self-specific environments of Chinese and non-Chinese patients having nasopharyngeal carcinoma (NPC) with those of healthy control subjects to identify particular patient-environment interactions that may play a part in the etiology of NPC. The research will pay particular attention to exposures to certain occupational environments and dietary patterns both of which are suspected, on the basis of previous research, of being associated with a high risk of NPC. The control subjects will be sampled from the general population to serve as comparison groups in the determination of relative risk. Information on the self-specific environments will be collected through structured and non-structured interviews of 110 patients, 160 control subjects and members of their families. Information will also be collected from investigations of job sites, residences, and neighborhoods. The interviews will seek information on the daily activity patterns of the participants spread over one week. The field work will be conducted in the State of Selangor, Malaysia. The research will clarify evidence for the association between poorer socioeconomic environments and NPC, and test various hypotheses, particularly that carcinogens are inhaled in certain industrial occupational settings, and that exposure to Cantonese salted fish is a high risk NPC factor. The research will also examine the value of using daily activity patterns as a basis for obtaining information about self-specific environments and the importance of this information in identifying possible environmental risk factors. The methodology could have application in studies of other cancers.

DIFFERENTIAL MORTALITY - COMPARATIVE STUDY OF SOCIOECONOMIC EXPLANATIONS

C.B. Nam, State University System of Florida, Florida State University, School of Social Sciences, Dept. of Sociology, *205 Wildwood Dr., Tallahassee, Florida* 32306 (SOC78-07298)

Death rates vary over the life cycle in a standard fashion, with mortality probabilities being highest at the infant and older ages. Nevertheless, when age curves of mortality are compared for different groups, they sometimes can be seen to intersect so that one group has higher death rates at younger and middle ages and lower rates at older ages. Past research has shown that this phenomenon is not solely due to erroneous data and is therefore partially a result of some type of selection in survival patterns. Explanations for why the pattern is observed in some cases and not others, and what produces it, will be sought in this study. A series of cross-national aggregate comparisons of mortality curves will be analyzed, including both crossovers and non-crossovers, and the effects of socioeconomic level, mortality level, and causes of death will be measured. The general hypothesis is that socioeconomically advantaged populations in all societies have prolonged life expectancies until old age, when mortality rates for the advantaged exceed the rates for the surviving disadvantaged. Cross-tabular and regression approaches will be used. The findings should be significant for understanding social aspects of health, survival, and the aging process, as well as for adding to our knowledge about social and racial stratification.

ENVIRONMENTAL QUALITY AND HUMAN PERFORMANCE

S.D. Roscoe, Illiana Aviation Sciences Ltd., *Box 2238, Station A, Champaign, Illinois* 61820 (DAR78-12722)

This project is an investigation of the effects of tobacco smoke in combination with other individually mild environmental stressors, such as the reduced atmospheric pressure, loud noise, and whole-body vibration encountered by passengers in airplanes, trains and busses. Sensitive measures of the depression or facilitation of human performance of concurrent tasks that require divided attention will be corre-

lated with affective psychological responses of irritation, anxiety, depression, narrowing of attention, slow thinking, and hostile responses not typical of the individual.

The objective will be to quantify the effects of these individually mild environmental stressors upon basic functional components of human performance representative of a wide range of tasks encountered in complex, demanding jobs. The anticipated results will be of fundamental scientific nature, generalizable to the development of regulatory quidelines and administrative decisions regarding environmental pollution levels and exposure limits in public conveyances.

WORKING CONFERENCE ON NUTRITION AND BEHAVIOR - NEW RESEARCH DIRECTIONS

B.E. Hindman, Franklin Inst. of the State of Pennsylvania, *20th & Benjamin Franklin Pkwy., Philadelphia, Pennsylvania* 19103 (OPA79-20650)

There is a great deal of controversy in the scientific community with regard to the definition of the exact relationship that exists between human nutrition and consequent measurable behavior both in the short and long term. The objective of this workshop is to bring this problem area into sharper focus.

The workshop will draw upon experts from the fields of nutrition, neurology/neurobiology/neurochemistry, psychology, psychiatry, physiology, pharmacology, toxicology, behavioral testing methodology, and epidemiology to discuss the present status of the research with regard to this problem and to identify new or additional status of the research with regard to this problem and to identify new or additional research directions.

Four commissioned papers, specifically relating nutrition to behavior from the vantage point of toxicology, physiology/neurochemistry, epidemiology, and pharmacology, will be written by experts in these fields. These papers will provide a sharp focal point to the workshop sessions and will help generate useful discussion. An expert organizing committee of four renowned researchers will develop the final agenda of defined subtopics.

The report and recommendations resulting from the workshop will be used as input to NSF to assist in program planning in Human Nutrition, and to Federal Drug Administration, US Department of Agriculture (Human Nutrition Center), and National Institutes of Health for use in future program development. The workshop will be held in Williamsburg, Virginia, in March 1980.

RESEARCH NEEDED TO IMPROVE DATA ON THE MINERAL CONTENT OF HUMAN TISSUES

M. Milner, American Inst. of Nutrition, *9650 Rockville Pike, Washington, District of Columbia* 20014 (OPA79-20493)

A major barrier to understanding the significance of minerals in human nutrition and health is the absence of an adequately organized, systematic data base dealing with the mineral content of various human tissues. This project would consist of a three-day workshop to critically evaluate current knowledge concerning the mineral content of human tissues, to assess the costs and sampling problems in obtaining this information, and to identify research needs and prioritries in relation to establishing an adequate data base.

The workshop will bring together experts in nutrition, medicine, epidemiology, pathology, physiology, and biochemistry. Ten commissioned papers will be written by appropriate experts to summarize the current state-of-the-art in measuring the content of various important minerals, such as zinc, copper, chromium, selenium, etc., in human tissue. Other topics will include mineral balance and the relation of specific minerals and various disease states.

The research agenda resulting from this workshop will be used as input for the National Science Foundation in program planning for its Human Nutrition program and to National Institutes of Health (National Institute of Arthritis, Metabolic and Digestive Diseases). Food and Drug Administration, Environmental Protection Agency, and U.S. Department of Agriculture for use in future program development.

The workshop will be held in Bethesda, Maryland, in May 1980.

ANNUAL CONFERENCES ON TRACE SUBSTANCES IN ENVIRONMENTAL HEALTH

D.D. Hemphill, University of Missouri, Columbia Campus, School of Agriculture, Dept. of Horticulture, *130 Jesse Hall, Columbia, Missouri* 65201 (PFR78-05696 A01)

The Thirteenth Annual Conference on Trace Substances in Environmental Health (June 4-7, 1979) is part of a continuing program of the University of Missouri's Environmental Health Program. The purpose of these Conferences is to explore the biological, ecological and health significance of chemical substances that may be present in 'trace' amounts in the environment. The Conferences are concerned with both organic and inorganic substances in our air, food and water. As a consequence, only a few selected areas can be considered in depth each year. These conferences form part of an overall interdisciplinary approach necessary to understand the complexity of environmental and ecological problems and methods for their control.

The grant continues earlier support under Grant PFR 78-05696 (Twelfth Conference).

The general areas for the Thirteenth Conference include: Epidemiology of Trace Substances, Environmental Pollution, Environmental Geochemistry and Health, Analytical Methodology, Metabolic and Health Effects of Chemical Substances.

ANALYSIS OF NONLINEAR MATHEMATICAL MODELS IN PHYSIOLOGY, ECOLOGY, AND EPIDEMIOLOGY

K.L. Cooke, Claremont Colleges, Pomona College, Undergraduate School, Dept. of Mathematics, *Claremont, California* 91711 (MCS77-04466 A01)

Continuation of MCS72-04965 A04.

In recent years, the importance of mathematical models in ecology, physiology, economics, etc., has been recognized. Since many of the phenomena under study involve nonlinear interactions, the models often lead to nonlinear equations. The purpose of this research is to continue the study of the formulation of such models and the rigorous mathematical investigation of the associated equations. Of particular interest are models which take into account time delays or hereditary dependence, and consequently most of the equations formulated are delay-differential or delay-integral equations, partial differential equations, or higher order difference equations. The importance of these delayed effects is well-recognized, but only in the last decade or so has the theory of these equations been sufficiently advanced to permit the successful resolution of the questions of interest in the applications.

For most of the equations a primary objective is to determine when there are equilibrium states and when these are stable, when there are stable solutions, and when more complicated behavior may occur. Another objective is to determine the extent to which this depends on the presence of delayed effects, and on the magnitudes of the delays. In the long run, it is anticipated that these studies, besides being of mathematical interest, will be of assistance to ecologists, medical researchers, and others, as they attempt to understand observed phenomena.

DISCUSSIONS OF CHEMICAL HAZARDS FOR UNION MEMBERS

J. Golodner, Labor Inst. for Human Enrichment Inc., *815 16th St. N.W., Washington, District of Columbia* 20006 (OSS78-24068)

Occupational health hazards are more and more in the forefront of today's news, although they have been with us in one form or another since the beginnings of technology. Current Government statistics show that American workers are exposed to large numbers of toxic chemicals which cause large numbers of deaths and diseases each year. Most workers do not have sufficient training or information to enable them to fully understand the problems and protect themselves. This proposal seeks to reach blue collar workers and to present to them the kind of technical information they need to increase their awareness of, and help them understand, occupational health problems. The education medium will be a play on occupational health, followed immediately by a discussion period between the audience and technical experts. This project is viewed in part as a pilot program to explore the utility of this approach. The play will be presented in union halls, at work sites, etc., in an attempt to communicate with blue collar workers who normally are not reached by such media as public TV, science writing, or museum exhibits.

In order to assure balance and objectivity, an advisory committee includes representatives of industry and labor as well as academic experts on occupational health.

EPIDEMIOLOGIC STUDIES OF CHAGAS' DISEASE IN SOUTHERN MEXICO

R.S. Goldsmith, University of California, San Francisco Campus, School of Medicine, Dept. of Epidemiology & International Health, *551 Parnassus Ave., San Francisco, California* 94122 (INT78-21361)

The proposed study of Chagas' disease brings to the task the talents of Dr. Robert Goldsmith and colleagues of the University of California, San Francisco, together with Dr. Fernando Beltan of the Mexican Center for Ecological Research in the southeast, located in San Cristobal, Chiapas State. Chagas' disease (American trypanosomiasis) is an infection of man and animals caused by the protozoa, Trypanosoma cruzi, and which is transmitted by many species of triatomine bugs which live in dwellings and animal nests. The disease is endemic in an area extending from Argentina to the United States.

Previous studies by Dr. Goldsmith in the Oaxaca and Chiapas States of Mexico have shown that a considerable number of people are infected. However, fundamental information is lacking to provide data needed to develop rational methods of control. The investigators will trap and study infected wild animals, radiotracking of animals back to their nests and biological and behavioral studies of the organisms which carry the pathogens. Susceptibility of the organisms to insecticides will be measured. Observations on humans will involve studies of cardiac effects of the disease. The Mexican Ministry of Public Health considers Dr. Goldsmith's studies on Chagas' disease to be important to be continued.

MEDICAL AND PHYSICAL STUDIES OF MERCURY IN THE ENVIRONMENT AT ALMADEN, C.R., SPAIN

R. Wilson, University of Rochester, School of Medicine & Dentistry, Dept. of Radiation Biology & Biophysics, *601 Elmwood Ave., Rochester, New York* 14627 (INT78-19907)

Mercury has been mined from the region of Almaden, Spain for two thousand years. Even today, the mines produce over one quarter of the world's mercury supply. The miners, residents and general environment of Almaden have thus been exposed to mercury at unusual levels for an extensive period of time.

This multi-faceted project involvng U.S. and Spanish scientists is directed at gaining a better understanding of the impact of mercury in the environment in and around the mining area. Studies are being carried out on the levels of airborne mercury in the town and the mines and on the occupational exposure of underground and refinery workers. Also, methods are being developed for assessing body burdens of mercury and for quantifying various diagnostic, therapeutic and prophylactic measures such as chelating agents.

HUMORAL IMMUNITY AND IMMUNOGENETICS IN PSORIATIC ARTHRITIS

F.B. Vasey, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Rheumatology Section, *13000 N. 30th St., Tampa, Florida* 33612 (501-44-4238)

The program is designed to investigate pathogenetic mechanisms in Psoriatic Arthritis (PsA). Immunologic factors, genetic influences and environmental agents are under study. Our previous work elsewhere produced evidence of immune complexes by Clq deviation in 40% of Ps and PsA patients. In the past further evidence supporting immune reactivity has been found in the form of apparently slightly elevated levels of serum cryoglobulins and definite elevations of serum IgA. Serum IgG and IgM have been normal. Greater numbers of patients and controls need study. Our previous studies showed a prevalence of BW38 in 40% of peripheral PsA patients. This finding was recently confirmed by a group at NIH who extended the observation to include an association with CW6 and DR W 4. B27 in central PsA patients has been frequently shown

We are currently typing at A,B,C, and DR loci. The number of patients studied since the laboratory opened is too few for useful observation at this point.

Increasing evidence is suggesting a role for bacteria and/or bacterial products in the pathogenesis of spondyloarthritis. Epidemics of Salmonella, Shigella, and Yersinian have led to B27 positive individuals to the development of 'reactive' arthritis which appears clinically similar to Reiter's syndrome. Klebsiella has been found in stool cultures and correlated with disease activity in AS. We are currently designing studies to examine the role bacteria and/or bacterial products could play in the pathogenesis of PsA.

AGENT ORANGE (DEFOLIANT) TOXICITY - FAT CONTENT OF DIOXIN IN STUDY AND VOLUNTEER CONTROL SUBJECTS

P.E. Donahue, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *820 S. Damen Ave., Chicago, Illinois* 60612 (173-34-2231)

Because of increasing concern that chemical defoliants used in Viet Nam may have long term pathologic effects, VACO has requested a number of hospitals in the Chicago area to study individuals exposed to chemical defoliants.

Because any detrimental effects of these materials are speculative at present it is important to identify individuals with documented exposure to such agents while in military service. Toward the end, a special questionaire designed by VACO has been employed and is being utilized to identify individuals who were at risk and have presented themselves for evaluation to V.A. West Side Medical Center.

Individuals will be screened with routine biochemical investigation and complete physical examination. Those with relatively well documented exposure will be asked to volunteer for a minor operative procedure which will remove a portion of fat from their abdominal wall.

This 25 grams of fat from the abdominal wall will then be sent to center laboratory at the University of Nebraska where it will be analyzed for residual chemical contamination. By this means it is thought that residual chemical which might be lodged in the fatty tissue can be documented as present or not present.

2.1357,

STUDY OF FREQUENCY OF HOSPITAL-ACQUIRED VIRAL RESPIRATORY INFECTIONS IN AN ADULT MULTI-BED WARD

R.L. Tabor, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Biloxi, Mississippi* 39531 (439-76-0221)

Hospital acquired respiratory infections are a well recognized problem resulting in increased patient suffering, prolonged hospitalization and increased risk of unnecessary antibiotic therapy. Although studies have been done on the frequency of hospital acquired viral respiratory infections in pediatric patients, a closer analysis is needed to evaluate the nature and extent of the problem in adult patients.

The purpose of this study is to determine the frequency of respiratory viral cross-infection among patients in an adult multi-bed ward. At the time of admission serum will be drawn from all consenting patients. A second serum will be drawn from any patient developing symptoms of respiratory infection, 10 to 12 days following the onset of symptoms. The second serum will be drawn from asymptomatic patients at time of discharge. The paired sera will be tested for rises in titers to respiratory viruses. Significant rises will be utilized as an indicator of infection. Clinical data from patient interview and chart review will include length of stay, onset date and symptoms of any respiratory viral infection, diagnoses, medications, history of influenza vaccine, age and race. Length of stay, age, diagnoses, bed location, medication and vaccine history will be evaluated as possible predisposing factors contributing to the acquisition of infection. The number and type of respiratory viral infections among the patients in the 12-bed ward will be reported. Hypothesis: Rises in titers to the same viruses will occur in those patients acquiring respiratory viral infections.

DIABETES INTERVENTION STUDY

F. Vinicor, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *1481 W. 10th St., Indianapolis, Indiana* 46202 (051-34-8588)

PROJECT OBJECTIVES: (1) Analyze impact of health professional and patient education on the knowledge, skill, and behavior of the professional and health outcomes of the patient. (2) Develop diabetic patient data base for epidemologic studies.

PLAN: Patients with D.M. are identified, informed consent obtained, and an extensive data base collected. Health professionals and all their patients are then randomly assigned to one of four groups: (1) Existing health patterns; (2) Patient education; (3) Professional education; (4) Patient and professional education. Educational interventions are systematically applied; professional and patient behavior and outcomes are observed.

METHODOLOGY: Patient assessment: history, physical exam, vascular analysis (doppler analysis), nerve conduction studies, fundus photography, bone mass and dental assessment. Patient and professional education includes intensive instructional-based concepts with innovative techniques (e.g. computer reminders, compliance training).

FINDINGS: 350 patients have been evaluated. The mean age is 58 years, mean age of onset at 48 years and mean duration of diabetes 10 years. 71% of patients are on insulin, 14% on oral agents and only 15% on diet alone. The mean percent IBW was 130% with a body fat of 37%. 1/4 do not understand an insulin reaction. Two thirds of patients believe diet is more important than urine testing but only 15% report they always follow the diet. The mean fasting blood sugar was 243 mg/dl, 2 hr pp blood sugar was 352mg%, and A1Hgb was 11.7%.

RELATIONSHIPS BETWEEN LEAD IN HOME DRINKING WATER, CARDIOVASCULAR RISK FACTORS AND OTHER HEALTH INDICES

A.J. Garvey, U.S. Veterans Admin., Dept. of Medicine & Surgery, Outpatient Clinic, *17 Court St., Boston, Massachusetts* 02108 (033-32-1192)

PROJECT OBJECTIVES: To examine relationships between lead and other trace metals found in home drinking water and indices of health, with particular emphasis on cardiovascular health.

PLAN: The study is being performed in collaboration with the National Heart, Lung, and Blood Institute (NHLBI) and the Environmental Protection Agency (EPA). Samples of home drinking water and nail clippings were collected from 325 Normative Aging Study (NAS) subjects in 1976-1977 and analyzed for lead and other trace metals by the EPA in Cincinnati. A follow-up collection of water and nail clippings was completed on the same subjects in August, 1979. These samples will also be analyzed by the EPA. Health data were collected as part of subjects' regular NAS physical examinations.

METHOD: A data set linking trace metal data from the 1976-1977 water samples to NAS health data was constructed by the NAS in August, 1979 and sent to NHI BI in Bethesda, Md. for statistical analysis. Frequency distributions of trace metal data have been obtained, and regression analyses relating hypertension to trace metal exposure controlling for age and other known risk factors will be performed.

FINDINGS: Lead levels in the Boston area were lower than those found in Glasgow and British samples. Nevertheless, 27 percent had casual samples above 50 micrograms/liter, and 52 percent had first morning samples above that level. Levels beyond 50 micrograms/liter are generally considered undesirable.

RISK OF HEPATITIS AMONG HOSPITAL PHLEBOTOMISTS

C.P. Craig, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Infectious Disease Section, *13000 N. 30th St., Tampa, Florida* 33612 (209-28-4083)

This research protocol is designed to evaluate the incidence of hepatitis among phlebotomists in hospitals. Data being collected from phlebotomist who will be bleeding every 2 months over a six month period include the following: 1) Exposure to oncology patients, 2) exposure to hemodialysis patients, 3) number of hours spent in drawing blood weekly, and 4) past history of hepatitis. Control populations will consist of phlebotomists working in voluntary blood banks and secretaries employed in participating hospitals. The study has been active for approximately 4 months and has already demonstrated that hospital phlebotomists have serologic evidence of previous hepatitis B in excess of the general population, approximately 20%. Completion date for the study is January 1, 1980.

INVESTIGATIONS ON LEGIONNAIRES' DISEASE

S.M. Finegold, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Infectious Disease Section, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (550-14-6341)

The Legionnaire's bacillus has recently been recognized as an important cause of serious forms of pneumonia. Wadsworth VAH has had an ongoing outbreak for approximately one year, with 33 documented cases, deaths, and a number of additional cases not yet studied serologically.

The proposed project would provide standard and advanced diagnostic tools, including those for microscpic, cultural and immunologic demonstration of the organism or evidence of its participation in the disease process. Studies will also be directed toward evaluation of autopsy material for the previous 3 years for evidence of the disease, epidemiologic information, biology of the organism, new diagnostic tools, antimicrobial susceptibility, and studies of possible toxin production.

PROSPECTIVE STUDY OF THE PREVALENCE OF LEGIONNAIRES' DISEASE IN VETERANS WITH PNEUMONIA

P. Edelstein, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Research Service, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (545-66-4479)

The work performed in the last year has been related to the clinical bacteriology and serology of Legionella pneumophila. Techniques of yolk sack inoculation, direct immunofluorescence (DFA) microscopy, indirect immunofluorescent serological techniques, and methods of primary isolation on solid media have been perfected. Twenty-five strains of L. pneumophila have been isolated from clinical specimens (blood-3, lung-8, transtracheal aspirate-10, endotracheal aspirate-4), using in vitro methods in all except one case. This represents about 1/3 of the known human isolates. The bacillus can be grown in primary isolation an average time of 5 days after inoculation. This is clinically useful, and has widespread application. A semi-selective medium which enables isolation of the organism from contaminated clinical specimens have been developed. A serological laboratory for determination of antibody titers against L. pneumophila has been established. Antibody levels against all four known serotypes are being tested for. Methods for the rapid diagnosis of the disease by DFA methods have been established. DFA examination of sputa has been helpful in the diagnosis of 19 cases of Legionnaires' disease at Wadsworth. Unfortunately, primarily because of the need to set up these techniques first, very few patients have been enrolled in the prospective study of pneumonia. However, tremendous progress in the sphere of clinical microbiology of the organism has been made. More patients will be studied in the near future. This work has resulted in the publication of seven papers. Several more manuscripts are in preparation, or have been submitted for publication.

PILOT STUDY OF THE RELATIONSHIP BETWEEN SMOKING AND PARKINSON'S DISEASE

R.J. Baumann, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Leestown Pike, Lexington, Kentucky* 40507 (329-34-8022)

Previous studies found fewer cigarette smokers among persons with Parkinson disease than among other patients. We reinvestigated this phenomenon utilizing nonpatient controls. One hundred and fifty (63%) of 237 cases and 224 (47%) of 474 controls never smoked cigarettes (p less than 0.001). Significantly different smoking rates were also present at 10 and 20 years before onset of Parkinsonism.

INVESTIGATION OF CERTAIN MEDICAL IMPLICATIONS OF AN IODINATED WATER SUPPLY

W.C. Thomas, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Gainesville, Florida* 32601 (266-52-6674)

Since 1963, the water supply of the Florida Correctional Institute at Lowell, Florida, has been iodinated, rather than chlorinated, as a means of water purification. During these years 177 of the inmates gave birth to 181 infants, and there were no detectable goiters in any of these newborns. Thirty-five of the inmates were hospitalized at the College of Medicine at the University of Florida to determine how quickly RAI uptakes would return to the normal range and whether perchlorate or diuretics would hasten the removal of accumulated iodine. These latter agents were only slightly effective in accelerating iodide excretion, and in untreated subjects RAI uptake values were within the range of normal after two to three weeks of using a noniodinated water supply.

EPIDEMIOLOGY AND CLINICAL SIGNIFICANCE OF NON-A, NON-D BETA HEMOLYTIC STREPTOCOCCI IN ADULT MEN

R.H. Parker, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Infectious Diseases Section, *50 Irving St. N.W., Washington, District of Columbia* 20422 (537-26-2718)

This study will investigate the prevalence of beta-hemolytic streptococci other than groups A and D in a hospitalized adult population and to correlate the recovery of these isolates with infectious and noninfectious diseases. Primary goals will be to define a carrier state for these microorganisms, to determine the significance of in-hospital acquisition of these microorganisms and to determine the effect of antimicrobial therapy on colonization and infection rates with these microorganisms.

PREVALENCE OF UNDETECTED DEPRESSION & HOPELESSNESS AND THE RELATIONSHIP TO THE USE OF MEDICAL SERVICES BY MEDICAL PATIENTS

H.L. Barnes, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Togus, Maine* 04330 (004-26-3732)

PROJECT OBJECTIVES: The purpose of this project is to investigate (1) the prevalence of undetected depression and hopelessness with patients who come to a medical/surgical outpatient clinic; and (2) if the level of depression and hopelessness is related to the excessive use of services.

PLAN: The Beck Depression Inventory (BDI), a self-rating scale, and the Hamilton Rating Scale for Depression (HRS), a clinical interview, will be used to measure depressive symptoms and the Hopelessness Scale (HS) for measuring symptoms of hopelessness. To factor out severity and extent of illness, the Seriousness of Illness Rating Scale (SIRS) will be used while also determining the relationship of these two factors to depression and hopelessness.

METHOD: Subjects will be male patients who come to the medical outpatient clinic of the Togus VA in Maine during a 3-6 week period of July/August, 1979.

CLINICAL RELATIONSHIP: Treatment and management plans for patients with detected depression and hopelessness could be implemented more efficaciously and lower the possibility of suicide or reduce utilization of ancillary medical services and to speed recovery for an illness.

NONINVASIVE ASSESSMENT OF CAROTID DISEASE IN HYPERTENSIVE SUBJECTS

G.E. Bone, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Vascular Surgery Section, *4500 S. Lancaster Rd., Dallas, Texas* 75216 (465-64-8052)

This study will assess the prevalence and natural history of asymptomatic carotid arterial occlusive disease in a population of patients with chronic arterial hypertension. The status of carotid arteries will be documented noninvasively by pulsed Doppler ultrasonic arteriography, periorbital Doppler cerebrovascular examination, and ocular plethysmography/carotid phonoangiography. During the initial 12 months, it is hoped to enter approximately 700 patients. Baseline studies will establish the prevalence and morphologic characteristics of carotid artery disease in this cohort. Each patient will be subsequently re-evaluated at periodic intervals over a subsequent 4-year period.

The results of this study may: 1) define the potential morbid significance, if any, of asymptomatic carotid artery disease, 2) clarify the relative contribution of carotid artery disease to stroke pathogenesis in the hypertensive patient, 3) enhance the existing fund of knowledge regarding the influence of recognized cardiovascular risk factors in carotid artery disease, and 4) establish the relative feasibility and cost-effectiveness associated with the various noninvasive techniques employed for routine and/or mass screening of stroke-prone populations.

IMMUNOLOGICAL MECHANISM AFFECTING INFECTION BY HERPES GROUP VIRUSES

M. Oxman, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Infectious Diseases Section, *3350 La Jolla Village Blvd., San Diego, California* 92161 (041-30-0453)

The objective of this research program is to identify specific immunologic defects in immunosuppressed patients which predispose them to severe infections by varicella-zoster virus (VZV) and other members of the herpes virus group, to develop practical methods for the assessment of relevant host defenses against these virus infections, and to develop and evalute practical methods for prophylaxis and therapy. Our aims are: 1) to develop practical techniques for the measurement of virus-specific humoral and cellular immunity to VZV; 2) to utilize these techniques to characterize the responses of normal individuals to primary (varicella) and recurrent (herpes zoster) VZV infections; 3) to apply these techniques in a prospective study of the natural history of VZV infections in immunosuppressed patients in order to determine which (if any) can be used to identify in advance patients at increased risk; 4) to determine the effect of prophylactic administration of VZV-immune globulin on the frequency, severity and complications of VZV infections in patients with Hodgkin's disease and non-Hodgkin's lymphoma; and 5) to attempt to adopt the techniques developed with VZV to the measurement of humoral and cellular immunity to cytomegalovirus (CMV) and herpes simplex virus (HSV) and then apply these to the prospective study of the natural history of CMV and HSV infections in immunosuppressed patients.

GASTRIC LESIONS IN RHEUMATOID ARTHRITIS PATIENTS

P.H. Guth, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Gastroenterology Section, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (562-36-8405)

Both aspirin and the new non-steroidal anti-inflammatory medications cause gastric mucosal injury. The proposed study is a prospective endoscopic analysis of the prevalence and characteristics of gastric lesions in rheumatoid arthritis (RA) patients on chronic aspirin or non-steroidal anti-inflammatory agent therapy. Three hypotheses are to be tested: 1) RA patients on chronic aspirin therapy have an increased prevalence of gastric lesions when compared to RA subjects on other non-steroidal anti-inflammatory agents or enteric coated aspirin; 2) gastric ulcers in RA patients develop after chronic aspirin ingestion (greater than 3 months); and 3) aspirin-associated gastric ulcer develops in the absence of antral gastritis. Two groups of RA patients will be studied. Group I will consist of newly diagnosed RA patients on no therapy who will be followed by endoscopy and biopsy over a 4 month period after institution of aspirin therapy. Group II will consist of previously diagnosed RA patients on chronic therapy (no less than 3 months) who will undergo one endoscopy and biopsy. Group II patients will be subdivided into 4 categories, those on 1) soluble aspirin, 2) enteric coated aspirin, 3) non-steroidal anti-inflammatory agents, and 4) indocin therapy alone. All endoscopies will be performed by an investigator unaware of the patients symptomatology and clinical status. All histologies will be interpreted by an investigator unaware of the patient's identity and point in the study at which it was taken. Results will be analyzed in terms of the hypotheses being tested.

INTERNATIONAL EPIDEMIOLOGY STUDY ON SMOKING PATTERNS AND LUNG CANCER

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (083-36-0408)

At the request of Enviro Control, Inc. and with the approval of the NCI, the principal investigator serves as pathologist in an International Epidemiology Study on Smoking Patterns and Lung Cancer. The goal of this study is to attempt to determine whether the tobacco used in cigarettes in the different countries will cause development of different histologic types of lung cancer. The benefit of one individual evaluat-

ing all the material is that there will be uniformity in the histologic evaluation.

A conference was held on June 7, 1979, with Dr. Thomas Owen of the NCI, Dr. Neil Lynch of Enviro Control and Dr. Christian Vutuc from Vienna, Austria, which should result in a better understanding between this laboratory and the individuals submitting slides for the study. Although we have not received slides for evaluation since June 1978, they will be sent again in the near future. Some of the countries participating in this study are: France, Germany, Austria, Italy, Scotland and Cuba. The Cuban pathologists have asked for a conference with the principal investigator in Cuba to discuss the format of the study and also WHO classification of lung tumors. The principal investigator will also examine material in a study of Cuban migrant workers in the Miami area who develop lung cancer. The contract for this study has been awarded and material should begin to arrive within the next six months.

EPIDEMIOLOGY, GENETICS, AND MOLECULAR BIOLOGY OF AMINOGLYCOSIDE RESISTANCE IN NOSOCOMIAL INFECTIONS

J.F. John, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *109 Bee St., Charleston, South Carolina* 29403 (201-36-1416)

This project is designed to examine the epidemiology of resistance factors carried by or characteristic of pathogenic gramnegative bacteria producing infection in hospitalized patients. New molecular techniques will be employed to characterize individual plasmids and these markers will then be used to determine the extent of R factor activity within given hospital. The aminoglycoside family of drugs has become very important in the therapy of serious infections in the hospitalized patient. We will study emergence and persistence of resistance to the aminoglycosides and determine the R-factor mediated resistance mechanisms for this group of drugs. By understanding better R-factor mediated aminoglycoside resistance, we hope to contain resistance to these agents and preserve their use as effective therapeutic agents.

SPECIFIC OBJECTIVES: (A) To determine the incidence and significance of R factor mediated aminoglycoside resistance in hospitalized patients using intensive surveillance of hospital wards and daily collection of aminoglycoside resistant isolates from the bacteriology laboratories. (B) To characterize these R-factors as to their molecular weight, patterns of self-transmissibility, elaboration of modifying enzymes, and coexistence of other resistance markers. (C) To determine the distribution and persistence in patients, hospital staff and environmental reservoirs of specific plasmids by obtaining cultures from medical personnel and the inanimate environment.

EPIDEMIOLOGY OF LEGIONNAIRE'S DISEASE IN A VETERAN POPULATION EXPOSED TO A MAJOR CONSTRUCTION PROJECT

D.P. Nicholson, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *300 E. Roosevelt Rd., Little Rock, Arkansas* 72206 (453-76-0494)

The overall objective is to provide further epidemiologic information concerning Legionnaire's Disease. The source of origin, mode of spread, and risk factors related to Legionnaire's Disease are not known, though speculation from previous epidemics indicates a possible relationship to building reconstruction and contaminated water air cooling systems. The specific aims will be: 1) Measure the endemic incidence of Legionnaire's Disease at the NLR Div. of the Little Rock VA Medical Center; 2) Measure seasonal variations in incidence of Legionnaire's Disease at the same facility; 3) test whether intensive construction and demolition of the facility over 3 years will significantly increase the incidence of Legionniare's Disease; 4) isolate the sources for both the endemic drift and epidemic outbreak, should they occur. Surveillance will be undertaken of the hospital population, personnel, and construction crew. Small samples of blood will be drawn for indirect fluorescent antibody tests against one or more antigenic strains of Legionnaire's Disease at the initiation of the study, and either estimated or stored as serum. All subjects entering the study will have further blood drawn for titres either on their anniversary, or on discharge, and repeated during subsequent re-admissions. Clinical incidence of Legionnaire's Disease will be monitored by similar investigation of unexplained febrile episodes persisting over 48 hours, and supported by other diagnostic means.

Subject profiles, data base, and continuing information will be collected and analysed by conventional techniques, involving considerable program analysis and computer time. A preliminary random survey of one quarter of the chronic patient population performed in January 1979, revealed that 12 percent had significant Legionnaire's Disease titres at greater than 1:128. Currently a similar survey of non-hospital veterans is being studied with the help of the state American Legion.

STUDIES ON STAPHYLOCOCCAL INFECTIONS

R.I. Wise, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Togus, Maine* 04330 (465-01-2392)

PROJECT OBJECTIVES: (1) To obtain specimens for isolation of Staph. aureus from the nose of all patients admitted to the hospital for one year, all employees and all infections of patients and employees. (2) To study the correlation of bacteriophage types of Staph. aureus with disease states, occupations of hospital employees and with infections. (3) To study the effects of antibiotic therapy on the carriage of Staph. aureus. (4) To compare types of Staph. aureus isolated from hospital employees carried by patients and their hospital acquired infections.

PLAN: The isolation of Staph. aureus was attempted on 4213 specimens obtained from the noses of 2583 patients on admission to the hospital from 401 employees and from 315 infections of patients and 20 infections of employees. All isolates were studied for Gram stain, hemolysis, coagulase, fermentation of mannitol, bacteriophage susceptibility and antibiotic sensitivity.

RESULTS: Total isolates numbered 1334. 90.8 percent were typeable. Significant changes have occurred in 25 years when results were compared to a similar study performed by the investigator in 1954. In 1954, bacteriophage types carried by hospital employees were similar to those causing nosocomial infections of patients and different from those carried by patients at time of admission. In 1977, the types are similar from all sources indicating a complete diffusion of 'hospital' types into the community. Carriage rates of Staph. aureus were 34.4 percent for employees and 25.8 percent for patients. Bacteriophage type 94/96 is predominant.

Correlations were not significant with occupations, diseases, treatment with antibiotics because of insufficient numbers in each group.

STUDY OF RELATIONSHIP OF SMOKING TO CANCER OF THE PANCREAS

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (083-36-0408)

Cancer of the pancreas is now the fourth leading cause of cancer death in the United States. Among the etiologic factors said to be associated with pancreatic cancer are occupational exposures and a history of diabetes. Cigarette smoking has also been associated with cancer of the pancreas.

Several years ago we made a preliminary analysis of specimens of pancreas taken from routine autopsies. Included in the study were 1,294 men whose smoking histories had been obtained from previous studies. Slides were put into random order identified only by a serial number and examined for any evidence of pathology, particularly for duct cells with atypical nuclei, and these findings were combined with the smoking history for each case. Atypical nuclei were found in ducts of the pancreas in 22 percent of the men who never smoked regularly, 46 percent of the men who smoked 1-9 cigarettes a day, 57 percent of the 10-19 cigarettes a day smokers, 66 percent of the 1-2 packs a day smokers and 75 percent of those who smoked 2 or more packs a day.

We decided to design a more detailed protocol for analyzing atypical duct cells in the pancreas which requires 30 sections to be taken from each pancreas obtained at autopsy from several hospitals in New Jersey and upstate New York. We have collected 2,313 pancreata since 1971. Of these, smoking histories have been obtained for 1,288 cases. We will continue to collect specimens until we have collected enough cases by age and smoking habits to begin our histologic evaluation. It is expected that we will begin our study this year.

DYSPEPSIA, PEPTIC ULCER AND ITS COMPLICATIONS

A.F. Ippoliti, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Gastroenterology Section, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (224-58-1319)

The purpose of this study is to evaluate dyspepsia in peptic ulcer patients and the complications of same. The dyspepsia study was delayed pending a request for NIH for funding and the presence of new epidemiologist.

This present study is designed to identify and characterize psychological and physiological variables in patients with dyspepsia but without ulcer (x-ray negative dyspepsia), as compared to duodenal ulcer and normal subjects. The study remained in an inactive status during the better part of last year. We are now ready to follow-up on the 65 subjects who were screened and defined to have a history of ulcer complications and the 85 subjects who were defined to not have any history of ulcer complications.

STUDY OF LEGIONNAIRES DISEASE AT THE NORTHPORT VA MEDICAL CENTER

R. Grossman, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Pulmonary Disease Section, *Middleville Rd., Northport, New York* 11768 (112-38-8006)

Legionnaires Disease was first described as a specific entity following the outbreak at the American Legion Convention in Philadelphia in July, 1976. Since then the legionnaires bacillus has been shown to be a relatively common cause of respiratory infection in many parts of this country and throughout the world. While many epidemic outbreaks have been identified, sporadic cases have been even more common. Studies of people without any history of acute illness have shown elevated antibody titers in many suggesting that asymptomatic infection is also quite common. To our knowledge, no study has investigated the prevalence of this entity in patients with chronic obstructive lung disease or in the general population on Long Island. We initiated the current study in order to obtain answers to these two questions. Analysis of initial results of this study revealed positive titers in 27% of 71 patients with COPD and in 16% of 45 patients without evidence of COPD. There was no statistically significant difference between these two values (p greater than .2). However, when the mean antibody titers were compared by the T test, there was a significant difference (p less than .02). We conclude that there may be a higher incidence of Legionnaires Disease in patients with chronic obstructive pulmonary disease and propose to continue this study. We plan to compare a group of patients with COPD with age matched control population.

PREVALENCE OF DEPRESSION AND CHARACTERISTICS OF THE DEPRESSED GERIATRIC PATIENT IN THE MEDICAL CLINIC

J.T. Okimoto, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *4435 Beacon Ave. S., Seattle, Washington* 98108 (547-50-4102)

OBJECTIVES OF PROJECT: 1) To validate two depression scales, the Zung Self-Rating Depression Scale (SDS) and the Popoff Index of Depression (ID), in geriatric patients; 2) to estimate the prevalence of depression; 3) to identify characteristics of depressed geriatric medical patients; 4) to describe medical utilization patterns of depressed geriatric medical patients.

RESEARCH PLAN: The depression rating instruments which will first be validated in a sample of geriatric medical patients will be used in mail survey of all persons 60 years and older enrolled in the MCCU. Prevalence of depression will be estimated and utilization patterns examined.

METHODOLOGY: The validation phase of the study will consist of comparing the instrument score results with psychiatric interveiw using Research Diagnostic Critera (RDC) for the diagnosis of Major Depressive Disorder. Instrument results from the mail survee will be subjected to both routine scoring methods and a discriminant analysis. The prevalence of depression will be estimated from instrument results. Diagnosis will be linked to medical service utilization data stored in the MCCU data bank, and analysis of the depressed and non-depressed groups will include demographic differences, lab test utilization, problems treated, medication ordered and rate of recognition of depression by the provider.

FINDINGS TO DATE: Both self-rating depression scales were found to statistically agree with psychiatric interview, although performance in this age group was lower than in younger subjects. Estimates of prevalence of depression in geriatric medical patients range from 25-35% depending upon the method of scoring. Further analysis is currently underway.

CASE CONTROL STUDY OF LUNG CANCER IN FORMER MALE RESIDENTS OF CUBA

M.B. Troner, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *1201 Northwest 16th St., Miami, Florida* 33125 (054-34-0287)

The Health Systems Division of Equifax is conducting a two year epidemiologic study on the health effects of different smoking habits. This study is being conducted under subcontract to Enviro Control, Inc. of Rockville, MD, for the Smoking and Health Program funded by the National Cancer Institute. Incident cases of lung cancer in Cuban males in the Miami/Dade County area will be identified and interviewed. Each case will be assigned an age matched (plus or minus 5 years) hospital and a neighborhood control.

Newly diagnosed cases of lung cancer will be identified through the pathology departments of participating hospitals. The physician of record will be contacted to determine the patients eligibility as a Cuban and to obtain consent to interview the patient. Hospital controls will be identified through records of hospital admissions and the same procedures for contacting attending physicians will be followed. Neighborhood controls will be located from a predetermined search pattern based on the address of a lung cancer case.

After signing a consent form, each subject will be interviewed about his work history, personal habits such as smoking, family medical history and diet. All cases and controls will be interviewed in the same manner by trained interviewers. The interviewers will not be aware of a subjects diagnosis or control status and all responses are held in confidence.

HISTOCOMPATIBILITY, VIRAL AND IMMUNOGENETIC FACTORS IN ALCOHOLIC AND NON-ALCOHOLIC CIRRHOSIS OF THE LIVER

N. Ravendhran, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *1201 Northwest 16th St., Miami, Florida* 33125 (213-82-2599)

The specific aims of the proposed study are threefold: first, to determine the frequency of the histocompatibility antigenic types in alcoholic, post-hepatitic, and cryptogenic cirrhosis: second, to determine the incidence of serological parameters of type A, type B, and non-A, non-B, hepatitis viruses among patients with alcoholic and non-alcoholic cirrhosis; and finally, to characterize the binding of immunoglobulin to hepatocytes in liver biopsy specimens from patients with alcoholic and non-alcoholic cirrhosis.

This study will be carried out in patients with chronic liver disease who have been admitted to the hospital for diagnosis and/or management of their liver disease and who would normally require a liver biopsy for proper management of their disorder. Demographic and pertinent historical data as it relates to chronic alcoholism and the epidemiology of viral hepatitis will be abstracted from the patient's medical records. Tissue typing, haptoglobin phenotypes, serological assays for the hepatitis viruses, autoimmune antibody determinations and standard liver chemistries, including serum bile salt analyses will be performed on blood specimens. In addition to the standard processing of the liver biopsy specimen for light microscopy, immunofluorescent studies will be performed to characterize the nature of immunoglobulin binding to hepatocytes.

The results of these studies should better elucidate the importance of genetic predisposition, viral hepatitis, and immunoglobulin binding in the pathogenesis of cirrhosis of the liver.

2.1380,

THE PREVALENCE OF CIRRHOSIS IN ALCOHOLIC CALCIFIC PANCREATITIS, AND THE CORRELATION WITH HLA TISSUE TYPING

N. Gitlin, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *2615 Clinton Ave., Fresno, California* 93703 (545-53-5219)

PROJECT OBJECTIVES: (1) To determine the prevalence of histologic cirrhosis in patients with alcoholic calcific pancreatitis, (2) to identify a possible genetic marker which may enable early identification of patients 'at risk' for alcoholic pancreatitis and/or alcoholic cirrhosis, (3) to establish whether patients who manifest both pathologies share a common genetic marker. The genetic marker will be sought by ascertaining whether certain HLA antigens are increased (or decreased) in patients with these disorders.

PLAN: Patients with calcific alcoholic pancreatitis will undergo secretin stimulated pancreatic function test, a fecal fat balance study, a liver biopsy and blood studies for tissue HLA, full blood count, protime, platelet count, protein electrophoreses, SGOT, bilirubin, cholesterol, alkaline phosphatase, amylase, calcium and gamma glutyml transpeptidase. Two control groups consisting of alcoholics without cirrhosis or pancreatitis and alcoholic cirrhotics without pancreatitis will be compared.

BENEFITS: The detection of a genetic marker indicating a predisposition to either alcoholic pancreatitis or cirrhosis or both would be a tremendous epidemiological and medical value. The true relationship between the present conflicting prevalence of liver disease and calcific pancreatitis will be established.

GROUP B STREPTOCOCCAL INFECTIONS IN THE NEWBORN

L.J. Fenton, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neonatal Biology Section, *Sioux Falls, South Dakota* (295-36-4274)

Epidemiological aspects of Group B Streptococcal (GBS) infection and specific properties of the GBS were investigated for this final year of the grant. An analysis of factors which predisposed to maternal colonization revealed that the use of estrogen pills prior to conception, maternal fever, and endometritis were significantly correlated with colonization. Infant colonization was significantly correlated with fever at delivery, vaginal delivery and a prolonged second stage of labor. The external auditory canal and umbilicus were the best sites for recovery of GBS in the infants; while vaginal, rectal and periurethral suds were equally satisfactory in the mother. Todd Hewitt Broth containing colistin and nalidixic was found to be an excellent selective medium and did not require blood for good recovery. CIE was only able to detect GBS in 50% of maternal cultures when applied directly to the initial broth containing mixed flora. There were no false positives, however. The function of the alternative pathway of was found to be mildly but significantly correlated with birth weight and independent of maternal illness. The hyaline membranes in babies who died from GBS sepsis and pneumonia and those who died in the first few days [illegible] IRDS were found to contain C3, IgG, C4 and factor B. A common inflammatory pathway is suggested with possible immune injury to alveoli. Finally, an endotoxin-like property was attributed to the GBS based on clinical, in vivo (animal) and in vitro studies.

THE EPIDEMIOLOGY OF NON-A NON-B HEPATITIS

R.E. Sampliner, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *3900 Loch Raven Blvd., Baltimore, Maryland* 21218 (294-36-2494)

OBJECTIVE: 1. To determine the frequency of non-A, non-B hepatitis among patients seeking medical attention for their clinical illness. 2. To define the epidemiologic characteristics a non-A, non-B hepatitis in relation to hepatitis A and hepatitis B.

PLAN: 1. All patients presenting to four Baltimore area hospitals with hepatitis will be identified. They will be administered an epidemiologic questionnaire and sera will be collected at the baseline and again in 6 months.

METHODS: 1. Hepatitis B will be defined by HBsAg and antibody markers to hepatitis B core and surface antigen. Hepatitis A will be defined by antibody to H hepatitis A. Non-A, Non-B hepatitis will then be defined as the absence of all of the above markers.

FINDINGS: To date, 105 patients with acute viral hepatitis have been idenfified and bled. Serologic tests are pending.

INTRAHOSPITAL TRANSFER OF PLASMIDS ENCODING FOR MULTIPLE ANTIBIOTIC RESISTANCE

J.J. Plorde, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Infectious Disease Section, *4435 Beacon Ave. S., Seattle, Washington* 98108 (476-32-6618)

We have investigated an epidemic of urinary tract infections caused by multiply-resistant Enterobacteriacease at the Seattle Veterans Administration Hospital. Twenty multiresistant Serratia marcescens and 15 isolates representing six other species of enteric organisms isolated during the epidemic were chosen for molecular analysis. Most of S. marcescens belonged to a single colicin type (16) and all of these contained a single 45 megadalton plasma. A similar plasma was found in the six other species. Conjugative experiments demonstrated this to be an R plasma encoding for resistance to 10 separate antimicrobial agents. Plasma restriction endonuclease cleavage studies revealed the R plasmids to be identical in the Serratia strains and the six other species. These data indicate that the antibiotic resistance seen in the epidemic strains were encoded for by a single conjugative R plasmid. This clearly demonstrates that our epidemic was caused by the spread of both an epidemic bacterial strain within the hospital and an 'epidemic' plasmid to a variety of Enterobacteriaceae.

THE EFFECT OF RETIREMENT ON PHYSICAL HEALTH

R. Bosse, U.S. Veterans Admin., Dept. of Medicine & Surgery, Outpatient Clinic, *17 Court St., Boston, Massachusetts* 02108 (022-22-8564)

This project began on September 30, 1979. a) OBJECTIVES: To examine possible changes in physical health related to occupational retirement and to detail the nature of these changes and the circumstances under which they occur. b) RESEARCH PLAN: The study population consists of 900 males (aged 50 plus as of 1975) from among the participants in the Normative Aging Study. The population is divided into two groups: (a) 380 men working at baseline physical examination but retired at follow-up exam; (b) 520 men employed at baseline and at follow-up exams. Retirees and their working-age peers will be compared for differential patterns of health change while controlling for intervening variables such as education, income, occupational type and attitudes toward work and retirement. In addition, the investigation will specify health change as to type of morbidity and examine whether changes in physical health are more prevalent at any particular time following retirement. c) METHODOLOGY: Health status at baseline and follow-up (3 years apart) will be assessed by self-report and by physical examinations. Physical exam data is currently available from the parent study, as is data from a pre-retirement questionnaire on work situation, health and lifestyle. Follow-up data on the work and retirement situations of the two groups will be collected in the course of this project. d) FINDINGS: First analyses show that retirees themselves report that retiring has had no negative effect on their health.

EPIDEMIOLOGY IN DENTAL STUDENTS

R.E. Sampliner, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *3900 Loch Raven Blvd., Baltimore, Maryland* 21218 (294-36-2494)

OBJECTIVE: To observe the frequency of HBsAg and anti-HBs in dental students. To define the incidence of sero-conversion with increased clinical exposure in dental school.

PLAN: To cross sectionally evaluate the entire school and then follow one class - the freshman class - through 4 years of training to see if with increased clinical exposure in the last 2 years of dental school there is an increased rate of sero-conversion.

METHOD: HBsAg and anti-HBs by radioimmunoassay.

FINDINGS: 29 dental students from all four years were evaluated. Two were found to have anti-HBs and none had HBsAg.

Project was terminated because of the inability to recruit substantial enough percentage of students.

CANCER IN LA. - A CASE-CONTROL STUDY OF LUNG, STOMACH AND PANCREAS CANCER

P. Correa, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *510 E. Stoner Ave., Shreveport, Louisiana* 71130 (256-52-7076)

The aim of this investigation is to identify factors associated with the high cancer rates that Louisiana has been shown to have. The study is designed to determine whether the excess in lung cancer mortality is due to smoking alone or to smoking in combination with other evironmental factors. An assessment will be made of the independent actions of various factors as well as their interactive and synergistic effects. Diet and occupational history will be especially important in assessing risk of cancers of the stomach and pancreas.

The study is a case-control design with noncancer controls matched to cancer cases on the basis of race, sex, hospital and age within five years. Additionally, certain medical conditions that have been strongly associated with smoking have been excluded as controls for lung cancer cases. The effect of this selection of controls should be to sharpen the contrast between the cases and the controls with respect to cigarette smoking and bring the other factors which are operating in lung cancer more sharply into focus.

Data will be gathered in face-to-face interviews by highly trained interviewers in the hospital or in the patient's home if a hospital interview is not possible. The interview contains residential, occupational, smoking and drinking water histories as well as information on diet, exposure to irritants and other questions.

Patients with cancer will be found in the files of the Pathology Department and Tumor Registry. Control patients will be found in admission records.

AN EPIDEMIOLOGICAL STUDY OF DIABETIC RETINOPATHY

J.J. Chosy, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *2500 Overlook Ter., Madison, Wisconsin* 53705 (271-26-1051)

OBJECTIVE: To study the prevalence and severity of diabetic retinopathy in a group of 2400 diabetic patients in their home communities.

RESEARCH PLAN: First year we will ascertain diabetics living in 11 county area. In the second and third years we will examine patients. In the fourth and fifth year we will analyze the data.

METHODOLOGY: We will objectively record retinopathy by use of stereoscopic fundus photographs combined with a standardized protocol for grading retinopathy. The association between the prevalence severity of retinopathy and risk factors such as smoking and blood pressure level will be examined utilizing analysis of variance and other statistical techniques for multiple variables.

RESULTS: Over 400 physicians are participating in study.

SMOKING AND LUNG CANCER - FEASIBILITY STUDY OF A DIAGNOSTIC TEST TO IDENTIFY PERSONS AT HIGH RISK

H.V. Samis, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Bay Pines, Florida* 33504 (218-24-5762)

The objective of this feasibility study is to assess a convenient, reliable and rapid in vitro virus trasformation assay for use as a diagnostic index to identify smokers who are at increased risk for development of lung cancer. To achieve this objective the research plan is aimed at identifying individuals from which skin biopsies and personal medical histories can be obtained within the following categories: (1) smokers and non-smokers with diagnosed lung cancer, different types of cancer, and debilitating diseases other than cancer, and (2) age-matched controls without medical histories of any of these infirmities. Data from these tests will be analyzed for significant differences in the absolute oncogenic virus dose that affects cell transformation and correlation with the occurrence of lung cancer in the particular patients. Although our findings deal primarily with cancer risk associated with smoking, we may also be able to identify other patients at risk such as those individuals exposed to asbestos and other agents considered as potential environmental carcinogens. In the event appropriate associations are demonstrated during this feasibility study, a large prospectus study in various VA populations will then be proposed. Further, cultured skin fibroblasts exhibiting divergent degrees of transformation will be examined to elucidate the basis for the inherent differences to possibly present clues as to the nature of the human oncogenic process.

TRACHEOBRONCHIAL TREE STUDY

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (083-36-0408)

During the past two decades tar and nicotine content of American cigarettes has been greatly reduced. Although lung cancer death rates have continued to increase, there has been evidence from recent epidemiologic studies that mortality rates over this same period have started to decrease. If reduction of tar and nicotine reduces the risk of lung cancer, then we would expect that histologic changes in the tracheobronchial tree in men who were autopsied in recent years to be less extensive than in men who died 15 or more years ago. If it could be shown that the degree of these histologic changes in cases that died in recent years (1979-1977) are less than in matched groups of cases that died in the 1955-1960 era, then it would lend considerable credence to the epidemiologic findings that reduced tar and nicotine content of cigarettes will result in lower lung cancer mortality.

A total of 182 cases that had been collected in the 1955-1960 era were matched with 182 cases who died in the 1970-1977 era. Cases were matched on age and smoking habits. We supplemented these records with 29 additional 1955-1960 cases and 52 1970-1977 cases. Fifty-five slides were prepared for each case, a total of 10,424 slides. After the cases were selected, the slides were placed in random order and identified only by a serial number. The findings on number of cell rows, percent with atypical nuclei, carcinoma in situ and early invasive cancer were recorded on code sheets and later key punched and combined by cases for analysis. The results of this study were published in the NEW ENGLAND JOURNAL OF MEDICINE 300: 381-386, 1979. In both periods the histologic changes increased with the amount of cigarettes smoked. Sections with advanced histologic changes (carcinoma in situ) occurred far more frequently in smokers who died in 1955-1960. Since all these subjects smoked cigarettes higher in tar and nicotine up to the time of death than those smokers who died in 1970-1977, the differences in findings can be attributed to the changes in tar and nicotine content of the cigarette they smoked.

A COOPERATIVE EPIDEMIOLOGIC AND PATHOLOGIC STUDY OF COLON-RECTUM CANCER

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (083-36-0408)

Colon-rectum cancer ranks second as a cause of cancer death in both men and women. There appear to be geographical differences in incidence, and some investigations have linked the development of these cancers to dietary factors.

In order to shed light on the incidence of undiagnosed primary colon-rectum cancers at autopsy, observe the location of polyps and malignancies found in the colon and determine if atypical lesions and polyps are found more frequently in the colon cancer case than in non-colon cancer cases, we set out to collect a large number of colon specimens from hospitals in New Jersey, New York State, and London. Since the start of the collection of material, about seven years ago, we have accumulated 2886 colon-rectum specimens.

The colons are fixed in formalin, cleaned and examined grossly for evidence of neoplastic lesions and mapped according to their location in the bowel. The lesions are removed and prepared for microscopic examination. The remaining colon is embedded in paraffin and sectioned for later examination. We have concentrated our efforts on 500 of these cases in which the colon-rectum was completely removed including the anal skin. The lesions are examined microscopically and the size, location and type of mucosal lesion are recorded. A paper reporting the results of this investigation has been accepted for publication in CANCER.

Every malignancy that was found in the lining of the bowel arose in a polyp. We now plan to make a microscopic study of the remaining bowel, in cancer cases from the London series that were removed at the time of surgery, to see if there is any evidence of different patterns of neoplastic changes.

PROSPECTIVE GENETIC STUDIES OF COLON AND LUNG CANCER

M.J. Swartz, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *4101 Woolworth Ave., Omaha, Nebraska* 68105 (507-30-0806)

To date, we have obtained information on smoking history, other social history, medical history and family history from 149 lung cancer probands and 123 controls. These data are currently being computer coded for purposes of statistical analysis. In addition, the families of six of these lung cancer probands have been studied in depth because of the presence of lung cancer in at least two first degree relatives within the family. Detailed questionnaire data has been obtained from all relatives who were willing to participate in this phase of the study. An effort has been made to confirm all cancer diagnoses reported among family members of the lung cancer probands through pathology reports, medical records and/or death certificates. VA pathology and medical records have also been obtained for each of the lung cancer probands.

TRI-COUNTY STUDY OF CANCER OF THE MOUTH, ESOPHAGUS, LARYNX, STOMACH, COLON AND RECTUM

S. Graham, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *3495 Bailey Ave., Buffalo, New York* 14215 (069-18-3175)

In this study, subjects are interviewed with regard to dietary habits, smoking, occupation, medical and dental history. We have interviewed 76 patients from the Veterans Administration Hospital since 1975. To date, we have not obtained enough data for definitive analysis; therefore, we have not reported any results or conclusions. However, preliminary analysis of 100 case/spouse and 100 control/spouse pairs to determine extent of agreement with regard to the subjects' dietary habits is under way. We plan to continue interviewing for approximately 2 more years.

IMMUNE RESPONSE IN INFLAMMATORY NERVOUS SYSTEM DISORDERS

S.D. Cook, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (001-28-8308)

We have carried out studies on the epidemiology, virology, and immunology of multiple sclerosis (MS) and the Guillain Barre Syndrome (GBS). Epidemiologic studies in MS have suggested a link between an animal virus (canine distemper) and multiple sclerosis. Increased neutralizing antibody to canine distemper virus was found to be present in MS sera as compared to controls. Our epidemiologic studies in the Guillain Barre Syndrome have shown age and seasonal predilections consistent with an infectious etiology. Approximately 20% of patients with GBS have evidence of an associated acute infection with cytomegalovirus (CMV) as indicated by four fold increases in complement-fixing antibodies, IgM antibodies, and tissue culture studies. A rapid screening test for CMV sera positive cases has been developed in our laboratory using a counter-immunoelectrophoretic method.

PSYCHODYNAMICS OF CANCER

R.S. Picard, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *510 E. Stoner Ave., Shreveport, Louisiana* 71130 (723-18-8761)

As of March 10, 1976, data from a structured questionnaire has been accumulated on the following cases: 1) 106 controls over 35 years of age: (a) of whom 65 are continuing smokers, (b) 29 smokers who have discontinued the habit for periods greater than 2 years, (c) 7 who have discontinued for a period of less than 2 years, (d) 3 who have discontinued, then resumed smoking; 2) 23 controls under 35 years of age; 3) 16 cases of lung cancer; 4) 37 non-control smokers, non alcoholics; 5) 61 alcoholics; 6) 8 controls of cancer other than lung; and7) 6 cases of non smoking alcoholics. Statistical analyses are not contemplated until at least data on 75 cases of lung carcinoma are compiled.

Study is being tentatively coordinated with addition of questions and cases from the Fox Chase Cancer Center, Philadelphia, PA, under the auspices of Claus and Marjorie Bahnsen, Ph.D.'s. We plan to have within 15 months for analysis: 1) the 75 cases of lung cancer, 2) 100 control smokers over 35 of over 10 pack years of cigarettes, 3) 10 control non-smokers (over 35 of under 10 pack years), 4) 100 controls of individuals under 35 years of age admitted the General Medical wards in a VA Hospital, 5) 100 alcoholics admitted for treatment on a long-term alcoholic program, 6) 100 alcoholics admitted to a General Medical ward, 7) 35 cases of non smoking alcoholics, 8) 35 cases of non pulmonary cancer. Childhood experiences, occupational hazard will be submitted to intergroup statistical analyses for significant differences.

FAMILIAL INCIDENCE AND MULTIPLE MANIFESTATIONS OF MEDULLARY CARCINOMA OF THE THYROID

G. Williams, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Endocrinology Section, *820 S. Damen Ave., Chicago, Illinois* 60612 (578-38-5346)

The purpose of this study continues to be to evaluate all family members of patients with diagnosed medullary carcinoma of the thyroid. This evaluation includes a) clinical evaluation, b) serum calcitonin by radioimmunoassay before and after calcium infusion, c) serum parathyroid hormone by radioimmunoassay, d) urinary catecholamine determination. In any patients in whom abnormalities are found, appropriate therapy will be carried out. In those subjects in whom the studies are normal, repeat studies will be done at 6 to 12 month intervals. In this way, this study should a) lead to early diagnosis and treatment of patients with medullary carcinoma of the thyroid before clinical manifestations are apparent, and b) yield additional information about the incidence, inheritance and natural history of this disease.

During the past year, 8 additional new patients suspected of medullary carcinoma of the thyroid have been evaluated, but the studies were normal in all of these patients. The one patient who was identified as a strong suspect for medullary carcinoma of the thyroid last year is in Europe and is not yet available for reevaluation. This patient will be more thoroughly investigated and family members will be evaluated as soon as she returns to this area.

This study continues.

MORBIDITY AND EFFICACY OF INFLUENZA VIRUS VACCINE IN HIGH RISK INDIVIDUALS

J. Lucas, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Martinsburg, West Virginia* 25401 (235-70-0067)

Three hundred four volunteers were initially enrolled from amongst the patient-members of the Domiciliary and the patients of the Medical Service at the VA Medical Center in Martinsburg. Ninety-four were later eliminated from the study, leaving a total study population of 210. One hundred sixty-five high risk patients accepted vaccination with commercially obtained, inactivated influenza vaccine (1975-76 bivalent vaccine) and constituted in the final experimental Group I. Group II was comprised of 30 high risk subjects who refused vaccin. Groups I and II were shown to be of comparable composition by age and indices of disease. There was no significant difference between the vaccinated and unvaccinated groups in the frequency of acute respiratory illnesses as determined by the 'new respiratory illness' reports completed by the physician assistants.

Conclusions are pending because the Bureau of Biologics, Food and Drug Administration, has not released the results of the serological studies. Therefore this project, started in 1975, is being terminated.

MULTIPLE SCLEROSIS IN A MIGRANT POPULATION

J.F. Kurtzke, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (133-16-2851)

We studied a unique population consisting of the offspring of Vietnamese mothers and French fathers who were born in Vietnam and bought to France to be raised. All but 72 of 3451 such individuals completed background and neurologic questionnaires. All with 'positive' answers on the latter were examined neurologically. The 3379 respondents had a median year of birth of 1948, a median year of arrival in France of 1957, and they had been resident in France a median of 18 years before interview in 1975. Twenty-five persons recorded positive answers to neurologic symptoms, and six others reported a history of seizures alone. A total of 16 had reported seizures: 7 with infantile febrile fits; 9 with afebrile seizure disorders.

Three cases of exacerbating-remitting MS were discovered, as well as three persons in whom MS could be suspected: one cervical myelopathy, one progressive paraparesis, one bilateral optic neuropathy. The three MS provided a crude prevalence rate for an 18-year cumulative risk) of 89 per 100,000. Their age-specific prevalence rate was 169 per 100,000 population age 20-29. Each measure was similar to such rates for Denmark and had lower 95% confidence limits that clearly exceeded expectations for Vietnam. This is further evidence that the risk of MS can be increased by migration in childhood from low to high risk regions.

EPIDEMIOLOGIC STUDY OF MULTIPLE SCLEROSIS IN U.S. MILITARY-VETERAN POPULATION

J.F. Kurtzke, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (133-16-2851)

Five thousand and three hundred five World War II and Korean conflict veterans who have been compensated by the Veterans Administration for multiple sclerosis (MS) were matched to controls on the basis of age, date of entry into military service, and branch of service. Case/control ratios for white males, white females, and black males were 1.04, 1.86, and 0.45, respectively. The coterminous 48 states, divided into three tiers on the basis of latitude, exhibited the well-known north-south gradient in risk: For all races and both sexes, case/control ratios were 1.41, 1.00, and 0.53 for the North, Middle, and South tiers. Both white females and black males showed this same north-to-south variation in risk. The case/control ratio for males of races other than black or white was 0.23, with possible deficits in risk for American Indians and Japanese-Americans. Filipinos and Hawaiian Japanese were significantly low-risk groups. These findings suggest that both a racial and a possibly genetic predisposition, as well as a geographically determined differential exposure to an environmental agent, are related to the risk of MS.

Migration between birth and entry into service is being studied. Migrants are defined as individuals born in one of the three north-to-south tiers who entered service from a different tier. For white males of WW II born and residing in the same tier, case-control ratios were 1.41 north, 1.04 middle, and .56 south. Northern-born migrants entering from middle and southern tiers had lower ratios and southern-born migrants entering from middle and northern tiers had higher ratios. Thus the risk of MS is clearly altered by site of residence before onset.

THE DIFFERENTIAL DIAGNOSIS OF ORGANIC BRAIN SYNDROME

B. Seltzer, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, G R E C C Program, *200 Springs Rd., Bedford, Massachusetts* 01867 (160-38-5373)

A total number of 190 patients with organic mental disease have now been extensively evaluated. The experience gained in examining these patients has contributed greatly to the work of one of the investigators (B.S.) in editing the section on Organic Mental Disorders of the Diagnostic and Statistical Manual of Mental disorders, Third edition (American Psychiatric Association).

Work is nearing completion on the constuction of a shorter examination protocol, or 'organic profile' designed to serve as a research tool to aid in the identification of patients with specifically defined organic mental disorders. Preliminary results show this to be quite accurate in identifying patients with senile and presenile dementia (of the Alzheimer type). In addition, it is also useful in identifying several other common organic mental syndromes. In the second phase of this work, the test will be validated.

We are continuing our neuropsychological study of praxis in dementia as well as clinical studies characterizing the mental disorders associated with chronic alcoholism. Finally, having identified a fairly large number of patients with Alzheimer's disease, we are performing sequential examinations of these patients to study the natural course of the disease and we are also collecting demographic and other epidemiologic data.

AMERICAN HEALTH FOUNDATION STUDIES

N. Spritz, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *1st Ave. at E. 24th St., New York, New York* 10010 (215-24-4788)

Tobacco-related cancers, myocardial infarction, emphysema and COPD continue to constitute a major source of death and disability in the U.S.. And yet these deaths and morbidity are largely preventable because of their association with tobacco usage. Results indicate that the risk of developing these diseases increases with quantity smoked, duration of the habit and, for lung and larynx cancer, with non-filter cigarette smoking. Risk of mouth, larynx and esophogus cancer among smokers increases with quantity of alcohol consumed. Larger amounts smoked and lesser cessation rates are noted among lower socioeconomic groups suggesting that these groups will bear an ever increasing proportion of the burden of tobacco-related cancers.

Risk factors for gastrointestinal tract cancers continue to be identified and monitored. These include certain lifestyle variables associated with dietary habits, as well as alcohol consumption. To date,

2,000 interviews have been obtained: 40% colon cancer cases, 25% gastric cancer cases, and 35% rectal cancer cases and matched controls. An association between large bowel polyps and the future development of colon cancer is being suggested by our data and we are continuing our efforts directed at discovering a possible common etiologic factor.

ALCOHOL DRINKING PATTERNS IN VETERANS

A.S. Wilson, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Alcohol Treatment Unit, *5000 W. National Ave., Wood, Wisconsin* 53193 (073-28-1036)

This project has collected data on the alcohol drinking patterns in three groups of veterans: a) veterans applying for admission to the VA Medical Center, b) veterans in the Alcohol Dependency Treatment Program, and c) veterans applying for assistance at the VA Regional Office in Milwaukee.

Differences in the quantity, frequency, and variability of alcohol consumed will be compared. In addition, the medical conditions of these veterans will be examined for their relationship to the drinking variables.

THIRTY-YEAR CLINICAL FOLLOW-UP OF SELECTED DEMYELINATING DISEASES

J.F. Kurtzke, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (133-16-2851)

Beginning in 1956 we studied intensively a group of all 762 white men diagnosed as MS and all 183 diagnosed as optic neuritis (ON) during military service in the US Army during World War II (see project 'Natural History of MS' #1 completed in 1977). We classified only about 2/3 of the former group as MS, and only 1/8 of the ON had come down with MS by the mid-1960's.

In 1973 we initiated a follow-up of these 945 men, to include neurologic and ophthalmologic examinations of the 624 living survivors (funded by the National MS Society). Intake ceased in July 1977. All cases with conflicting data on diagnoses or clinical or pathologic (autopsy) findings have been reviewed, and all information has been encoded and placed on computer tapes. Major goals are to define (1) diagnostic criteria for MS (2) survival in MS (3) progression rates of ON to MS (4) early predictors of late course of MS.

No results are as yet available.

FALLS OCCURRING IN HOSPITALIZED PATIENTS - STUDY OF INCIDENCE

J. Graebner, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Nursing Service, *1601 Kirkwood Hwy., Wilmington, Delaware* 19805 (395-68-7758)

The pattern of falls occurring in an acute care VA facility was studied as falls among patients is the most common form of hospital accidents. Ninety-six falls occurred over a period of 3 months, giving a rate of about one fall per every 100 admissions. This incidence is the same as that of a general community hospital (Manyam, N.V.B. and MacKinnon, H.H., Nova Scotia Med. Bull. 52:23-25, 1973). Most falls occurred during the first week of admission, especially the first 3 days. Falls occurred mostly during 'care hours' ie., between 6 A.M. and 2 P.M. Being confused and/or going to bathroom remained the major reason for patients to get out of bed that resulted in a fall. Seventy-nine patients had a single fall; 13 patients fell twice; 3 had fallen thrice, while one patient fell 6 times. The incidence of falls were highest on Thursdays and lowest on Fridays. Sixty percent of falls resulted in non injuries; 5% of falls resulted in pain, but no detectable injury; 28% resulted in erythema, contusion or abrasion; 3% resulted in laceration requiring suture and two patients suffered fracture of a major bone. No deaths occurred within 24 hours following a fall.

The data indicates that the pattern of falls in an acute care VA facility is identical to that of a community hospital except that in the VA facility, most falls occurred during 'awake hours' rather than during 'sleep hours.'

IMMUNOHISTOPATHOLOGIC STUDY OF LEISHMANIA TROPICA AND TRYPANOSOMA CRUZI - IMMUNOGLOBULIN STUDIES IN PATIENTS WITH CHAGAS' DISEASE

D.N. Reifsnyder, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *Bay Pines, Florida* 33504 (134-28-4437)

The epidemiological survey of toxoplasmosis is now being prepared for submission to journal publication.

Studies have shown that antibody-coated bacteria in the urine are indicative of upper urinary tract infection. Applying this finding as hypothesis to pulmonary infection it was postulated that since sputum normally contains saprophytic bacteria and at times pathogenic bacteria that are not causing infection that if antibody-coated bacteria were detectable that these might prove to be cause of pulmonary infection. IgA is the immunoglobulin principally secreted by the respiratory epithelium. Thus sputum smears could be stained using fluorescein labelled antihuman IgA globulin to determine if a correlation could be made between those found on smear and subsequently cultured. Sputum smears were stained using standard immunofluorescent techniques. Sixteen unstained and 10 gram-stained smears were tested. The results indicated that gram-stained smears are poor samples for immunofluorescent staining. Previously non-gram-stained smears revealed a large amount of background IgA which did not permit a specific localization of bacteria. This is due to the fact that the secretions contain IgA which is produced in response to antigenic challenge. Further studies are now in progress to determine if the material containing the IgA material can be separated from the bacteria. Additionally, studies are being initiated to determine if specific species antibody may be helpful in elucidating the pathogenic organisms present. Should these be promising a detailed protocol will be submitted for funding consideration.

STUDY OF TRANSMISSION OF HEPATITIS B TO HOUSEHOLD CONTACT

R.E. Sampliner, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Gastroenterology Division, *3900 Loch Raven Blvd., Baltimore, Maryland* 21218 (294-36-2494)

OBJECTIVES: 1) to determine the frequency of hepatitis B markers in the household contacts of chronic carriers of HBsAg vs. the household contacts of negative controls. 2) to look for epidemiologic clues as to potential routes of transmission. 3) to determine if a chronic carrier is an ongoing source of infection to household contacts.

PLAN: Have all participants fill out an epidemiological questionnaire. Household contacts will be rebled 6 months after their baseline bleeding to determine cero-conversion.

METHODS: Blood samples (20 ml) are obtained from each consenting household contact - index case and index control. Serum samples are analyzed for HBsAg, anti-HBc, anti-HBs and liver enzymes. In addition, each HBsAg positive subject will be evaluated for HBeAg and anti-HBe.

FINDINGS: 422 household contacts of 157 chronic carriers of HBsAg detected at voluntary blood donation were tested. Findings in relation to the e antigen reveal that a significantly greater prevalence of HBV markers was detected in spouses of carriers with HBeAg (70%,7/10) than in spouses of carriers with anti-HBe (32%, 12/38, p equals 0.03). 41% (9/22) of all contacts of carriers with HBeAg had an HBV marker compared to 33% (73/221) of contacts of carriers negative for both HBeAg and anti-HBe and 25% (44/176) of contacts of carriers with anti-HBe: these differences are not statistically significant. In conclusion, HBeAg in carriers was associated with a significantly greater prevalence of HBV markers among spouses.

HEPATITIS BS ANTIGEN POSITIVE HEALTH WORKERS

R.E. Sampliner, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *3900 Loch Raven Blvd., Baltimore, Maryland* 21218 (294-36-2494)

OBJECTIVE: To determine those factors which may serve as markers of transmissibility in health care workers who are chronic carriers of HBsAg and to attempt to define those health care workers who represent special risks to their environment.

PLAN: To study the families of health care workers who are chronic carriers of presumed intrafamilial transmission.

METHODS: The status of liver involvement will be determined by liver function tests and liver biopsy, but only when clinically indicated. Sera will be evaluated for HBsAg, subtype of HBsAg, HBeAg, anti-HBe, anti-HBc and anti-HBs. The health workers precise role in relation to patients will be carefully identified, especially in regard to the performance of penetrating procedures on patients.

FINDINGS: Too few chronic HBsAg carrier health workers were identified to carry out the study.

ROLE OF ESTROGENS AS A FACTOR IN CANCERS OF HEAD AND NECK

W. Guerra, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Head & Neck Surgery Section, *Togus, Maine* 04330 (119-05-7911)

OBJECTIVE: To determine presence of specific estradiol receptor proteins in squamous cell tumors of head and neck as related to hepatopathology (alcoholism). The method chosen was a thin layer gel filtration assay (TLG) deemed suitable because high affinity of binding of (3H)17beta-oestradiol to cytosol has been observed despite the presence of relatively high levels of nonspecific binding components, another advantage being that only a small amount of tissue sample was required (50 mg). Materials were assembled and appropriately tested: (Tris-EDTA) buffer, sonifier for disruption of cells, Sephadex for gel plates, TLG-apparatus, filter paper for transfer of radioactive material and scintillation counter. Expertise was obtained in methodology by performing numerous tests on cow/calf endometrium. Tissue was processed at 0-2 degrees C. The pH of Tris-EDTA buffer was adjusted to 7.4. Nafoxidine was used for controls. Sephadex G-150 proved suitable. Inclinations of the plate were tried at various degrees; 25-35 degrees worked well. Radioactivity was recovered from gel plates with paper replicas and scintillation counter was used for determination. Results with endometrial tissue were as anticipated. Two separate cancer tissue specimens were used and significant specific estradiol uptake was recorded.

PLAN: In view of the encouraging results, repeated application of method and utilization of equipment will be carried out to maintain a high level of expertise. Calf endometrium will be used intermittently until 15-20 cancer specimens become available for this project. One half of each cancer specimen will be stored at 0 degrees to minus 5 degrees C. and another half at minus 60 degrees C.

IN VIVO MEASUREMENT OF CADMIUM AND OTHER METAL BY PROMPT-GAMMA NEUTRON ACTIVATION ANALYSIS

S.H. Cohn, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Middleville Rd., Northport, New York* 11768 (323-14-0928)

Absolute levels of Cd in the kidney & concentrations of Cd in the liver were measured in vivo in 20 healthy adult males. The Cd contents of their liver & kidney were measured by PGNAA using 238Pu,Be neutron sources. Organ Cd levels of smokers were significantly elevated above those of non-smokers. Average total body burden of Cd in men at age 50 was estimated to be 19.3 mg for non-smokers and 35.5 mg for smokers (36.7 pack/yr smoking index). Biological halftime for Cd in the body was estimated to be 15.7 yr (10-33 yr). Cigarette smoking was estimated to result in the absorption of 1.9 ug of Cd per pack. No relationship was found between body stores of Cd (liver and kidney) and Cd or Beta-microglobulin levels in urine and blood. Currently, the neutron activation facility is being mounted on a 34 ft. mobile trailer unit. With the support of ILZRO, this unit will be used to monitor levels of Cd in industrial

workers. The relative expense and the sophisticated expertise required to mount such a program may limit the availability of the technique to small scale research-oriented needs, for the future, at least. Nevertheless, it is anticipated that critically important data, particularly on industrially exposed workers, will provide a better basis for determining critical concentrations and for the setting or revision of standards for industrial and environmental Cd pollution.

INCIDENCE AND PROGNOSIS OF CANCER IN ALCOHOLICS

M.W. Morgan, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Surgical Service, *Biloxi, Mississippi* 39531 (426-34-7435)

The purpose of this project was to determine the incidence and prognosis of cancer in alcoholics. It has been suggested by previous studies that cancer incidence is higher in alcoholics, especially in certain locations of the body. This investigator has a clinical impression that cancer in alcoholics also has the worse prognosis.

As planned, the records of all patients admitted to the Biloxi V. A. Medical Center for five years, 1968 to 1973, with diagnosis of a malignancy and alcoholism were sought. Thirty such patients were identified, but with diligent effort ten of the records could not be located. Because of this, no valid conclusions can be drawn from the information obtained. The information will be retained for possible future use.

HLA B27 RELATED ARTHROPATHIES - GENETICS VERSUS ENVIRONMENT

A. Calin, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Rheumatology Division, *3801 Junipero Serra Blvd., Palo Alto, California* 94304

A rheumatologic questionnaire was developed and validated by use in three patient populations: a) patients with HLA B27 positive ankylosing spondylitis, b) B27 negative patients with mechanical spinal disease and c) control subjects. Five questions were shown to be highly sensitive and selective in distinguishing inflammatory from mechanical spinal pain; 1) insidious onset of back pain, 2) age of onset below 40 years, 3) persistence of pain for at least three months, 4) association with morning stiffness and 4) improvement with exercise.

This questionnaire is now being sent to some 200 first degree relatives of 100 patients with ankylosing spondylitis, 100 patients with Reiter's syndrome and other seronegative spondylarthritides. Clinical, radiological and HLA assessment is being performed on individuals who have an apparent inflammatory spondylarthropathy.

SPONTANEOUS BACTERIAL PERITONITIS

A.S. Barritt, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Gastroenterology Section, *Salem, Virginia* 24153 (099-40-9819)

This project was conceived to look prospectively at patients with cirrhosis of the liver and determine the incidence of a specific complication - spontaneous bacterial peritonitis. The only procedure involved is an abdominal paracentesis and there have been no complications in the 50 patients entered so far. The incidence of peritonitis is 6% to date.

Original plans were to include at least 50 patients. Because the incidence of peritonitis has increased in the second year of the study, I plan to continue to a total of 100 patients. There were 0 cases of peritonitis in 20 patients during the first year and 3 cases in 30 patients during the second year.

AUTOMATIC CARDIOVASCULAR DATA PROCESSING

H.V. Pipberger, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *50 Irving St. N.W., Washington, District of Columbia* 20422 (579-52-0549)

Trend analysis of ECGs from patients with Coronary Artery Disease (CAD), Hypertensive Cardiovascular Disease (HCVD) and Chronic Obstructive Pulmonary Disease (COPD) was continued and a total of 1,741 follow-up ECG records were collected during the last year. A risk index for CAD is being developed at the same time, based on a prospective study on CAD in Albany, NY, under the direction of DR. Joseph Doyle. Approximately 1,600 normal subjects above the age of 40 have been examined annually and an ECG record was mailed to the VAMC Washington, D.C., for computer analysis. Up to the present, close to 130 subjects developed a 'cardiac event', defined as myocardial infarct and/or cardiac death. Pre-event ECG records of these subjects were compared with serial records from subjects who did not develop an event. Highly significant differences were found. It is planned now to combine the predictive information derived from the ECG with other risk indicators such as cholesterol, hypertension etc., in order to arrive at a single risk index.

The data collection from children at seven medical schools is proceeding satisfactorily. Records from 4,116 normals and 3,334 abnormals are available now. Of the latter 2,116 had cardiac catheterization, thus providing objective evidence for the diagnosis of cardiac abnormalities. Once sufficiently large samples of normal and abnormal records are obtained, diagnostic classifications will be performed on the basis of multivariate analysis.

Exercise electrocardiograms have been collected from 300 normals and 513 patients with CAD. The data collection has been completed and computer programs for data analysis are being developed.

A LONGITUDINAL AND CROSS SECTIONAL STUDY OF ORAL HEALTH IN HEALTHY VETERANS

H.H. Chauncey, U.S. Veterans Admin., Dept. of Medicine & Surgery, Outpatient Clinic, *17 Court St., Boston, Massachusetts* 02108 (031-12-1877)

PROJECT OBJECTIVES: (1) Determine the incidence, distribution, changes, and interrelationships of oral variables used to indicate oral health, oral disease, and oral functional status; (2) Obtain descriptive observations, and patterns of association for the oral variables, both with one another and with variables measured in the Normative Aging Study (NAS); (3) Gather a detailed description and analysis of the effect of age on oral tissues and functions as well as elucidate the natural history of oral diseases.

PLAN: This oro-facial study includes six series of examinations or procedures: 1) Interim health history; 2) Oro-facial examinations; 3) Tests of masticatory function and survey of dietary habits; 4) Biochemical analyses of stimulated whole and parotid saliva; 5) Intra-oral and cephalometric radiographs, standardized photographs and study models of the teeth; 6) Oral cytological examination.

METHOD: Details of the procedures for recording these examinations have been described previously. All data are encoded on magnetic tape and more than 1,250 items are available for interdisciplinary evaluation with the biomedical and psychosocial data continuously evolved from the parent (NAS) study and other affiliated programs.

CLINICAL RELATIONSHIP: Age and four of the six periodontal disease variables (plaque, pocket depth, bone loss, and tooth mobility) were significantly different for persons with a removable partial denture. These differences continued to exist even after adjustment was made for age, calculus and plaque differences. Examination of persons with intact, partially compromised, and comprised dentition indicated that masticatory function, as measured by performance tests, did not significantly alter with age. A statistically significant interrelationship existed between the sodium chloride taste threshold and the amount of table salt used. There was a significant correlation between age and the sodium chloride taste threshold, as well as between age and salt use.

AN EPIDEMIOLOGICAL SURVEY OF SYMPTOMS IN DEPRESSION

W.W. Zung, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *508 Fulton St., Durham, North Carolina* 27705 (101-22-4743)

PURPOSE: Depression as a diagnostic entity consists of signs and symptoms, which if based on organic changes in the central nervous system should manifest similar psychopathology regardless of country or culture. Several previous reports generated from this investigation showed that by applying a standard measurement of rating using an operational definition of depression as a psychiatric disorder, we were able to show that patients having similar severity of depression in different countries of the world (as assessed by interviewer-clinician), have similar depression ratings when self-rated.

RESULTS: Data generated from the USA has been exchanged with a collaborator in Australia, Dr. Don Byrne, and validity and reliability studies of the depression rating scale have been established in Australia.

ASBESTOS BODIES IN ORGANS OTHER THAN LUNG IN OCCUPATIONALLY EXPOSED SUBJECTS

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (083-36-0408)

It has been generally thought that asbestos bodies are only found in the lung. Recent reports of the finding of asbestos bodies in the brain could have some particular significance in carcinogenesis in occupationally exposed workers.

With the cooperation of Dr. Alfred Conston of Somerset Medical Center, Somerville, New Jersey, we identified 39 subjects who had died with mesothelioma, asbestosis, or pleural plaques mentioned on the autopsy report at the hospital in 1970. Tissue samples from all available organs obtained at autopsy were prepared, ashed and studied microscopically for asbestos bodies in accordance with procedures previously developed at this laboratory. The analysis has been completed and accepted for publication in CHEST. In subjects occupationally exposed to asbestos, large amounts of asbestos bodies were found in lungs, and in most of these cases, asbestos bodies were found in many of the other organs examined. In 18 of the 39 cases with only pleural plaques found at autopsy, fewer asbestos bodies were found in lungs. The number of other organs

with one or more asbestos bodies ranged from 32% to 62% of the sites examined.

PERIPHERAL LUNG CANCERS ARISING IN SCARS

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (083-36-0408)

It has been our impression that scar cancers of the lung have been seen more frequently at autopsy in recent years than in the past.

To test this hypothesis, we studied the autopsy protocols and reviewed the slides for 1,186 cases of lung cancer over a 21 year period. A total of 89 peripheral cancers related to scars were found, constituting 1% of all autopsies and 7% of lung cancers. The proportion increased from less than 2% in 1955-1959, to 16% in 1970-1975. Seventy-two percent of the scar cancers were adenocarcinoma. No relationship was found between amount of smoking and scar cancer. The paper was published in CANCER 43:636-642, 1979.

VAOPC PSYCHIATRIC DIAGNOSTIC AND FOLLOW-UP PROJECT - PHASE I

W.A. Burr, U.S. Veterans Admin., Dept. of Medicine & Surgery, Outpatient Clinic, *17 Court St., Boston, Massachusetts* 02108 (580-03-7016)

PROJECT OBJECTIVES: To investigate the long-term course of non-psychotic psychiatric disorders and to study determinants of early mortality.

PLAN: To expand the sample size and to develop means of assessing smoking and alcohol use history among both living and deceased subjects.

METHODS: Record, review and design of interview protocols.

CLINICAL RELATIONSHIP: The project should lead to improved prognostic assessment of non-psychotic disorders, and should help outline genetic and familial factors.

MULTIPLE SCLEROSIS IN THE FAROES

J.F. Kurtzke, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (133-16-2851)

From 1920 to July 1977 there have been 25 cases of MS among native-born residents of the Faroe Islands. Age at onset average 26 years and the sex ratio was equal. Clinical features were typical of other series; 22 were exacerbating-remitting and 3 were progressive from onset.

All cases but one began between 1943 and 1960; one began in 1970. The 24 cases by year of onset follow a log-normal distribution and thus meet criteria for a point-source epidemic. All patients had been born by 1940. The early-onset cases (1943-1949) were in patients age 11-45 in 1940, and 8/10 late onset (1952-1960) were age 10 or less in 1940. Cumulative risk of MS in 1940 was 8.7 per 10,000. British troops in large numbers occupied the Faroes for five years from April 1940. During the war all but three patients lived where troops were stationed and these three also had contact with the British.

With continued support from the National MS Society and the Danish MS Society we are continuing clinical surveillance. Detailed 30-page questionnaire has been administered to patients, relatives, neighbors, and distant controls. HLA-typing and serum antibody levels have been done on the same groups. Death certificates for all Faroese 1900-1977 have been recoded to 8th ISC. British war diaries have been obtained.

HEPATITIS B CARRIER STATE AND THE SURGICAL PATIENT

T.W. Kiernan, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (137-34-5656)

Two nonconsecutive surveys were undertaken to determine if surgeons are at undue risk at this facility to the carrier of hepatitis-B-surface antigen. History, general lab studies, and serology for hepatitis B were studied and correlations developed. The study does suggest that the surgeon is a risk; high incidence of transfusion history in patients; high incidence of hepatitis-B-surface antibody and a significant presence of hepatitis-B-surface antigen in patients. Neither History or general lab studies gave away the presence of the potential hepatitis carrier state.

THE EPIDEMIOLOGY OF MULTIPLE MYELOMA

H.J. Cohen, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Medical Service, *508 Fulton St., Durham, North Carolina* 27705 (054-32-0582)

This is a retrospective and prospective case control approach to the investigation of the epidemiology of multiple myeloma. Studies focus on occupation with particular emphasis on radiation and on details of socio-economic class and medical history. Approximately two-thirds of the data concerning the retrospective studied cases have been abstracted, as have about 15% of the control data. The expected number of cases have been interviewed prospectively, but only 1/6 of the intended controls have been completed. A number of interesting tentative findings have thus far been derived from the data. These include: 1) A four-fold increased risk of multiple myeloma in first order relatives 2) Familial aggregation of multiple myeloma and demyelinating disease syndromes resembling multiple sclerosis. 3) Possible association between multiple myeloma and occupational low level radiation. 4) No apparent association between multiple myeloma and high socioeconomic status or diseases of immunity, allergic disorders, or chronic infections.

The study is continuing with the expectation that the required number of cases in control abstracts will be completed within the next year and one half.

HEPATITIS B VIRUS INFECTION IN AN ONCOLOGY UNIT

L.B. Seeff, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *50 Irving St. N.W., Washington, District of Columbia* 20422 (338-43-5556)

The intent of this study is to define the incidence and prevalence of Hepatitis B Virus markers in the staff assigned to the Oncology ward. Other scientific studies have already identified Oncology ward staff and patients as being in a high risk area. We would like to show evidence of type B hepatitis and to take steps toward limiting the transmission of of the virus. All staff have been assured that their right of confidentiality will be protected. This is necessary to protect indviduals against unreasonable actions such as endangering their jobs and/or preventing upward mobolity. There are 86 persons entered into the study which is proceeding without complications. There are no preliminary conclusions to be drawn because the nature and design of the study must be continued until completion before an analysis of the data can be made.

INVESTIGATIONS CONCERNING THE ETIOLOGY OF 'IDIOPATHIC' ACHALASIA

M. Mellow, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *50 Irving St. N.W., Washington, District of Columbia* 20422 (145-34-6675)

Thus far, 13 patients have been entered into our research study, entitled 'Investigations Concerning the Etiology of 'Idiopathic' Achalasia'. As expected, since the study simply entails venipuncture, no complications have occurred. No defect in general immunologic status or presence of autoantibodies have been observed thus far. Data relating to presence of anti-viral antibodies and HL-A typing has not been analyzed as yet. Since patients entered into study have had varying radical and socioeconomic backgrounds, factors which may influence relative prevalance of anti-viral antibodies (socioeconomic) as well as HL-A type (racial background) it is necessary that more patients be entered into study for meaningful statistical analysis.

STUDY OF TRANSIENT GASTRIC HYPOCHLORHYDRIA

C.T. Richardson, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Gastroenterology Section, *4500 S. Lancaster Rd., Dallas, Texas* 75216 (450-66-9086)

These experiments are designed to study spontaneous hypochlorhydria and gastritis. We are continuing to search for the cause of this phenomenon. We have developed a pepsinogen assay and will utilize this blood test to search for sporatic cases of hypochlorhydria. Preliminary studies have suggested that serum pepsinogen concentration increases as patients develop hypochlorhydria. Therefore, this test can be used to screen a large number of people. In addition, we will evaluate the epidemiology of this condition and will measure gastric acid secretion, serum gastrin concentration, and intrinsic factor concentration.

IDIOPATHIC IGM DEFICIENCY AS A PREDISPOSING FACTOR FOR BACTEREMIA

G.R. Hodges, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Section of Infectious Diseases, *4801 Linwood Blvd., Kansas City, Missouri* 64128 (279-36-1678)

The present study was undertaken to determine (1) if patients with bacteremia have a greater prevalence of IgM deficiency than matched controls, (2) if the IgM deficiency is transient or stable, and (3) if IgM produced by patients with IgM deficiency is specific for the organism causing their bacteremia. In the last year 41 patients with bacteremia and 36 matched controls were entered into the study. To date IgG, IgA, and IgM concentrations have been determined for all patients. Agglutination antibody, IgM antibody, and IgM antibody titers to the infecting organism of the patients with bacteremia have been determined. Analysis of the data showed no difference between the patients with bacteremia and the matched controls.

HEARING PROFILES OF A DOMICILED VETERAN POPULATION

D.K. Smith, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Audiology & Speech Pathology Service, *Martinsburg, West Virginia* 25401 (308-54-1067)

The primary purpose of this study was to: 1. Determine the hearing profile of a domiciled veteran population. 2. Compare this profile with that found in a similar non-veteran population. 3. Identify those domiciled veterans with significant hearing loss.

To accomplish this, Audiology and Speech Pathology Service, VAMC, Martinsburg, WV, administered an

audiologic test battery to 358 consecutive Domiciliary patient-members at the time of their annual physical examination.

Computer Science services at WV University were utilized for analysis of the data.

Evaluation of the data reveals a steady decline in pure tone thresholds, speech reception thresholds, and speech discrimination ability with an increase in age. This finding is consistent with other published studies which have been concerned with the relationship between reduced auditory acuity and advancing age.

Comparison of mean pure tone thresholds for the total population studied (N equals 358, average age 60 years) with those reported in a Public Health Survery (1962) suggests increased severity of hearing loss in a domiciled veteran population. The significance of noise exposure in a veteran population is discussed. Of the 358 patient-members tested, 7% (or 25) had speech reception thresholds of 30 decibels or poorer in the better ear; 12% (or 45) had discrimination ability of 80% or poorer in the better ear.

AN EPIDEMIOLOGIC STUDY OF AMYOTROPHIC LATERAL SCLEROSIS AND OTHER MOTOR NEURON DISEASES

J.F. Kurtzke, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (133-16-2851)

Deaths coded to amyotrophic lateral sclerosis (ALS) for the years 1963-1967 among U. S. males were matched against military files to identify 504 World War II veterans. Military controls for these 504 men were matched on year of birth, date of entry into military service, and branch of service. Hospital records of 37 representative deaths coded as ALS among veterans were reviewed and 36 were accepted as definite ALS. Military records were abstracted for information about preservice demographic and other factors, the physical examination for entry into service, and the medical history and factors characterizing the military career during World War II.

There was a deficit of blacks with ALS which did not attain statistical significance (P equals .08). Several differences in preservice occupations were found: truck drivers and 'operatives' were in excess. There was no significant difference between ALS cases and controls in aggregate scores on sports activity before service although baseball was more often listed by the ALS cases than by controls. The ALS patients significantly more often gave histories of trauma or surgical operations before service, and during service had a significant excess of hospitalizations for trauma and in particular for fractures of the limbs.

Still in process is analysis of a hospital case (ALS)-control (brain tumor) questionnaire, and a hospital case series of ALS. Study continues.

2.1430,

EFFECT OF URANIUM ON THE TRACHEOBRONCHIAL TREE

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (083-36-0408)

It has been established from epidemiologic studies of uranium miners and asbestos workers that the combination of cigarette smoking and heavy exposure to an occupational carcinogen can significantly increase the risk of lung cancer as compared with smokers without such occupational exposures. It has also been found that the remaining tracheobronchial tree in patients with lung cancer had extensive histological changes compatible with exposures to a carcinogenic agent. These changes include extensive basal cell hyperplasia with cells with atypical nuclei, loss of cilia, carcinoma in situ and early primary invasive cancers presumably not related to the main tumor mass.

We have recently completed a study designed to evaluate the changes in uranium miners compared to non-miners. One hundred and five uranium miners who died of lung cancer were matched on age and smoking habits to non-miners. A total of 28,928 slides were examined. Carcinoma in situ was found in 96 percent of slides in miners and 92 percent of non-miners. Degree 2 and 3 atypias in carcinoma in situ were more commonly found in the miners. A paper reporting results has been published in CANCER 42:483-489, 1978. The data indicate that the synergistic effect of cigarette smoking and uranium exposure increases the risk of lung cancer and that other sites of tissue alteration leading to tumor development are frequently present in the lung.

We are continuing to collect and examine the lungs received from Grand Junction, Colorado, and Butte, Montana, - 383 to date.

SACCHARIN AND BLADDER CANCER

C. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (083-36-0408)

It has been suggested from results of some animal studies and one retrospective epidemiologic study that sacchrain use increases the risk of bladder cancer. We felt we could test this hypothesis by studying the changes in the epithelium of the bladder in a large number of autopsies. Saccharin users will be matched for smoking habits and occupational exposures with non-saccharin user controls.

A protocol from sectioning the bladder has been made - about 60 slides will be available from step sections of the bladder. A form for obtaining histories of saccharin use, smoking habits, and occupational and residence histories from relatives has been designed and tested.

Specimens have been collected from a large number of hospitals in upstate New York and in other parts of the country. To date we have collected 582 bladders.

APPLICATION OF CYTOGENETICS TO MANAGEMENT OF PSYCHIATRIC PATIENTS

L.F. Jarvik, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Psychogenetics Unit, *Wilshire & Sawtelle Blvds., Room 209, Los Angeles, California* 90073 (128-14-0988)

The Psychogenetics Unit has been engaged in a variety of research endeavors. These include: 1. The effects of cannabinoids on human chromosomes. A prospective study of the chromosomal effects of orally administered delta 9-THC, the major psychoactive component of marihuana, cannabinol, cannabidiol, and placebo was carried out. Utilizating both the conventional method of chromosome analysis (i.e., breaks and structural rearrangements) and the sister chromatid exchange technique, a more sensitive indicator of chromosome damage, no increase in chromosome damage was detected over the duration of the study. 2. A double-blind study to assess the effects of BL-3912A in geriatric patients. B1-3912A is an amphetamine like compound but a weak psychostimulant and without the undesirable side effects. 3. Serum immunoglobulin (Ig) levels and cognitive performance in the impaired elderly. The investigation of the interrelationshp between serum Ig levels and intellectual functioning is continuing and larger sample sizes are being collected. 4. Chromosome changes with age and the relationship to intellectual functioning. Continued chromosome evaluation of patients on the Geriatric Psychiatry Ward. Chromosome banding procedures are also being utilized. 5. Glial cell chromosomes. To further extend the chromosome loss and intellectual functioning relationship detected utilizing leukocyte cultures, we are attempting to culture glial cells (tissue obtained at autopsy) for the purpose of replicating the leukocyte chromosome findings. 6. Coding and analysis of life-history information from a 30-year longitudinal study of aging twins. Data on health, stress, family history, education, nutrition, and many other variables are being classified and keypunched to permit multivariate analyses. The results will supplement prior publications from this data set on intellectual functioning, chromosome changes, and psychiatric disorders.

SMOKING AND DIABETIC RETINOPATHY

A.M. Potts, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *800 Zorn Ave., Louisville, Kentucky* 40202 (282-26-0773)

Diabetic retinopathy is one of the principal causes of blindness in the United States. A recent publication has suggested that cigarette smoking causes an increase in incidence of retinopathy in diabetics. The experimental approach in the cited paper is not completely sound and no investigation of individuals with mild diabetic retinopathy was performed. We propose to investigate the question in a rigorous manner to attempt to give a definitive answer to this important problem. The project seems to be well within the scope of the Tobacco and Health Institute since it will confirm or deny the connection between smoking and a significant disease.

A COMPARISON OF VARIOUS ALCOHOLISM SURVEY INSTRUMENTS AND AN INITIAL ESTIMATE OF THE PREVALENCE OF ALCOHOLISM IN THE PROVIDENCE VA HOSPITAL

G.M. Johnston, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Chalkstone Ave., Davis Park, Providence, Rhode Island* 02908 (011-48-7868)

This Hospital has applied for funds for an Alcohol Treatment Program for Fiscal 1979. If this is funded, it will be necessary to know the true prevalence of alcoholism amongst the patient population and to have a system for screening all patients for alcoholism. A number of alcoholism survey instruments are available - both questionnaires and biochemical measures; but there is insufficient published information available to chose between them for the present purpose.

In this project a random sample of 100 inpatients and 100 outpatients will be asked to fill out questionnaires and provide samples for biochemical measurement. They will also be assessed clinically by the principal investigator as to whether the patient is alcoholic according to the criteria of National Council on Alcoholism. This information will be processed to find which instrument or combination of instruments best distinguishes the alcoholics from the non-alcoholics. The data will also allow an initial estimate of the true prevalence of alcoholism.

Subjects will be asked to: A. Fill out three self-report questionnaires relating to their drinking behavior (CAGE, Michigan Alcoholism Screening Test, and Alcoholic Stages Index Subscales) B. Give samples of: blood (35 ml) to measure serum gammaglutamyl transpeptidase, alpha amino-n-butyric acid/leucine ratio and mean corpuscular volume; urine for measurements of urinary coproporphyrin; breath for an estimate of blood alcohol level. C. Undergo a clinical assessment for criteria of alcoholism.

INCIDENCE OF AVASCULAR NECROSIS IN PATIENTS ADMITTED TO AN ACUTE ALCOHOLIC TREATMENT CENTER

R.D. Lynch, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Wrightsboro Rd., Augusta, Georgia* 30904 (238-74-1188)

There has been difficulty in obtaining adequate x-rays of patients admitted to the Alcohol Treatment

Unit. The technician who was involved with this recently is a sophomore medical student and is not with us any longer because of school commitments. Therefore, the protocol as shown was instituted to make a routine frog leg lateral of the pelvis with all admissions and a brief questionnaire summary. This should allow us to collect the data and continue our incidence study.

The initial 200 patients involved in this study showed a surprisingly low incidence of avascular necrosis. One man with avascular necrosis had already had total hip surgery on the opposite side so he was known to have had avascular necrosis. The second man with some limitation upon physical examination had questionable avascular necrosis.

The initial incidence is much lower than anticipated and was indication for continuation of this study.

COOPERATIVE STUDY OF THE PATHOGENICITY OF THE SICKLE CELL TRAIT AND G-6-PD DEFICIENCY

P. Heller, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *820 S. Damen Ave., Chicago, Illinois* 60612 (577-42-8338)

The results of the first phase of this study have been published (N. Eng. J. Med. 300:1001-1005, 1979). Data on the future medical history of these patients will be assembled in regular intervals and, therefore, this study will remain active. Moreover, the accumulated material has been and will be used for further studies e.g. measurement of racial admixture, influence of alpha-thalassemia on the proportion of Hb S in individuals with the sickle cell trait and others. Analysis of the data on the proportion of Hb S has been completed and is being prepared for publication. Definite bimodal distribution of this proportion has been detected with approximately 12-15% of this population having a percentage of Hb S less than 35%. Although the information on the MCV of the erythrocytes is not optimal, there is a definite tendency for this population to have a lower MCV justifying the postulate that there is a high incidence of alpha-thalassemia trait in this group.

A STUDY OF THE INCIDENCE OF INFECTION IN CLEAN UNSHAVEN INCISIONS

J.A. Jacobey, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Middleville Rd., Northport, New York* 11768 (524-26-4536)

The reports of Altmeir and Cruse indicate that, although esthetically undesirable, it may be safer not to shave the patient's peri operative skin even though Cruse showed that not shaving the operative site decreased infection by half (a study of 3,649 cases) prior to surgery. Since this concept represents a significant departure from currently accepted practice it would seem to merit further investigation. For this reason, a blinded controlled series of patients subjected to general, cardiovascular and thoracic surgery are being studied to see if a statistically significant difference in incident of incision infection can be demonstrated between patients shaven immediately before and patients not shaven before surgery.

STUDIES IN INFECTIOUS DISEASES - VIRAL RESPIRATORY DISEASES

G.G. Jackson, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Section of Infectious Diseases, *820 S. Damen Ave., Chicago, Illinois* 60612 (528-18-9269)

The epidemiology of Influenza among patients in the WSVAH and Medical Center personnel was investigated. Influenza A (H3N2) caused an abrupt epidemic among persons over 25 years of age. In younger ambulatory people a new strain (during the past 20 years) caused some cases of milder respiratory disease. The simultaneous circulation of two distinct serotypes of Influenza A in the same season is unique. The older population with immunity to the new emerging strain (H1N1) continued to show acute Influenza with a strain closely related to that of recent years (H3N2).

The transmission of Influenza A among mice by natural cage exposure of one infected mouse to 4 or 5 cagemates, usually sibs, showed only occasional transmission detected by virus recovery from the lungs. The system was developed to test the effect of anti Influenza drugs on viral transmission. However, the model was too erratic in the results.

HISTOLOGIC CLASSIFICATION OF LUNG CANCER IN PERSONS EXPOSED TO ASBESTOS

O. Auerbach, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, *Tremont Ave. & S. Centre St., East Orange, New Jersey* 07019 (083-36-0408)

Studies of uranium miners who died of lung cancer have shown a pattern of histologic types different from the pattern demonstrated in non-miners who die of lung cancer. Although there have been some studies of histologic types of lung cancer in asbestos workers, these studies were conducted on small series only and did not make use of the WHO classification of tumor type.

With the cooperation of Dr. Conston of Somerset Medical Center, Somerville, New Jersey, we have collected tissue specimens (autopsy and surgical specimens) from all subjects diagnosed with lung cancer in a 25 year period. Asbestos exposed and non-exposed persons were included. Smoking, occupational and residence histories were obtained from families of the deceased. These subjects were matched on age and smoking history with persons who died of lung cancer in the Veterans Administration Medical Center in East Orange, N.J. Cases will be read in random order.

NOTES ON THE ETIOLOGY OF MULTIPLE SCLEROSIS

J.F. Kurtzke, U.S. Veterans Admin., Dept. of Medicine & Surgery, Medical Center, Neurology Service, *50 Irving St. N.W., Washington, District of Columbia* 20422 (133-16-2851)

Further work on migrant studies stresses the need for expectations of MS risk by age at entry, duration of residence, and age at observation (study/prevalence date). Data have been presented that a cohort of a disease-free population, all ages, would incur only 12 percent its own lifetime risk of MS after 5 years, and only 1/2 this risk even after 20 years. Analysis of time-course of the occurrence of MS in Iceland suggests that an epidemic of MS took place there too. This work is in progress.

STUDIES OF THE EPIDEMIOLOGY, PATHOGENESIS AND PREVENTION OF NEONATAL BACTERIAL DISEASES

G.H. McCracken, University of Texas, Health Science Center at Dallas, Southwestern Medical School, Dept. of Pediatrics, *5323 Harry Hines Blvd., Dallas, Texas* 75230 (R-270-79)

OBJECTIVES: The principal aims of the proposed studies are four-fold: 1. To rapidly identify infants with bacterial disease. 2. To gain further insight into the epidemiology and pathogenesis of neonatal bacterial infections. 3. To define the pharmacokinetics of antibiotics in low birthweight (less than 1500 grams), premature infants in order to assure safety and efficacy of these drugs. 4. To evaluate the effect of prophylactic antibiotics on microbial colonization and disease rates in newborn infants.

APPROACH: We propose seven areas of investigation that are designed to provide information on: (1) the epidemiology and pathogenesis of neonatal bacterial diseases, particularly those caused by the groups B and D streptococci; (2) techniques of rapidly identifying infants with bacterial infections; (3) the possible causes of 'clinical sepsis' in neonates who have sterile blood cultures; (4) the pharmacokinetics of aminoglycosides in infants less than 1500 grams at birth and (5) chemoprophylaxis of early onset group B streptococcal disease.

CURRENT PLANS AND/OR PROGRESS: We are currently assessing different methods to diagnose early-onset bacterial disease of newborns. The tests being evaluated are white blood cell and differential count, C-reactive protein, erythrocyte sedimentation rate, buffy coat smear and gastric aspirate analysis. Further, we have enrolled approximately 10,000 newborn infants into a prospective, randomized, controlled study of penicillin prophylaxis (versus topical tetracycline ophthalmic ointment) for prevention of gonococcal conjunctivitis and of early onset group B streptococcol disease. We plan to continue this project for a minimum of 20,000 deliveries. The other projects (listed under Approach) will be initiated in July-August, 1979.

PREVALENCE OF ACTINIC CHEILITIS AMONG THE RURAL POPULATION IN THE SOUTH OF CHILE

B. Martinez, PLAPO, *Jose Miguel de la Barra 475, Casilla 1903 Correo Central, Santiago, Chile*

OBJECTIVES: To establish the prevalence of actinic cheilitis in the farming population during the summer months and compare it to the prevalence during the winter. To determine the relationship of this lesion with hypermelanogenesis of the cheeks, the possible co-existence of the two lesions and/or the sequence of appearance of the lesions. To establish the relationship of hyperpigmentation with some factors such as ingestion of wine or apple alcohol (apple 'chicha'). At the same time, the prevalence of other lesions of the oral mucosa (especially precancerous lesions: leukoplasia, erythroplasia), lichen planus and recurrent oral aphtae will be determined in the same population.

APPROACH: Odontology students in their last semesters of study are provided with basic knowledge regarding the mentioned lesions followed by training specific to the region under study. The students are assigned to perform a house-to-house survey of all inhabitants over 15 years of age on certain islands in the Chiloe Archipelago. The islands have been selected based on ethnic, social, cultural and economic considerations.

PROGRESS: To date 860 surveys have been completed. They are being processed at the Computer Center of the School of Engineering, University of Chile. The survey questionnaires are based on a World Health Organization questionnaire that has been modified for use specifically within this region.

CLINICAL STUDIES OF OCCUPATIONAL BRONCHIAL ASTHMA

S.M. Brooks, University of Cincinnati, School of Medicine, Dept. of Environmental Health, *Eden & Bethesda Aves., Cincinnati, Ohio* 45221

These studies are an attempt to improve the definition of mechanisms and identification of etiologic agents causing occupational asthma. Data are obtained from humans exposed in laboratory inhalation studies or in the work environment. Laboratory concentrations are below the threshold limit values. A number of specific agents have been studied including isocyanates (toluene diisocyanate), various wood dusts (western red cedar, quillaja bark), phthalic anhydride, hexahydrophthalic anhydride, and other chemicals.

Studies include detailed immunologic and physiologic investigations such as bronchial provocation inhalation studies using various concentrations. Information on both immunologic and nonimmunologic factors is obtained.

BRAIN INJURIES AND PROTECTIVE SPORTS EQUIPMENT

E.A. Ripperger, University of Texas, Austin Campus, School of Engineering, Dept. of Aerospace Engineering & Engineering Mechanics, *200 W. 21st, Austin, Texas* 78712

This is a continuing study of the basic mechanics of head injuries, based on the premise that the neurosurgeon diagnosing and treating head injuries is in a better position for making his diagnosis and for determining the course of the treatment needed, if he knows the mechanism by which the injury was produced and the area of the brain most likely to be affected by that mechanism.

These studies have now been broadened to include the evaluation of protective sports equipment, with

particular emphasis on protective helmets. The national operating Committee on Standards for Athletic Equipment has issued a set of specifications for football helmets and the NCAA now requires that helmets which meet these specifications be used in games played under the jurisdiction of NCAA.

Unfortunately the acceptance or rejection criteria in the NOCSAE specifications are based on data published several years ago. These data are given in the form of a curve of acceleration versus duration of acceleration. The curve is known in the industry as the Wayne State University Tolerance Curve. Most authorities will probably agree that this curve leaves something to be desired as an injury criterion. Nevertheless, since it seems to be the best that is available it is used. The standard testing procedure based on the WSU Tolerance Curve provides essentially a go - no go decision with little indication of the comparative performances of different helmets. The objectives of this research are to develop procedures for making comparative evaluations, and to correlate these evaluations with injuries actually observed on the football field and elsewhere. It should be possible, in time, to determine what conditions produce concussion, and how helmet construction affects those conditions.

Our preliminary test results indicate that there are noticeable differences in helmet performance and there is some correlation between the make of the helmet and the incidence of head injuries.

PESTICIDE MONITORING

J.C. Street, Utah Higher Education System, Utah State University, Agricultural Experiment Station, Dept. of Animal Dairy & Veterinary Sciences, *Main Bldg., Room 104, Logan, Utah* 84321 (0078933)

OBJECTIVE: Assist the Human Effects Monitoring Branch, Office of Pesticide Programs, U.S. Environmental Protection agency, in determining the magnitude of human exposure to pesticides, providing expert consultant service to review, analyse, and validate pesticide risk and benefit data, conducting epidemiologic studies of various exposed population groups, devised means of recognition and diagnosis of pesticide effects in man.

APPROACH: Maintaining an inventory of pesticide usage in the study area (Utah) and use patterns; make human blood, milk or other tissue analyses in collaboration with the national monitoring program; establishing a group of certified consultants and coordinating their data review; development of methods suitable for population and environmental monitoring; developing special studies of pesticides health effects; and participation in Pesticide Incident investigations as needed in the study area and elsewhere on request of the OPP.

THE ANAEROBIC FLORA OF MAN AND ANIMALS IN DISEASE AND HEALTH

W.E. Moore, Virginia Polytechnic Inst. & State University, Anaerobic Bacteriology Lab., *P.O. Box 49, Blacksburg, Virginia* 24061 (0060025)

OBJECTIVE: Provide basic information about the anaerobic bacteria of man and animals, particularly as they relate to tissue infection, metabolic disease, and natural health state.

APPROACH: Isolate and characterize the anaerobic bacteria from infections and normal flora. Study bacterial metabolic systems, genetic and antigenic composition, nutritional requirements, and host-microbial as well as microbial-microbial interactions.

PROGRESS: Studies by 9 faculty and 10 graduate students demonstrate: An H(2)-uptake hydrogenase isolated from N(2)-fixing Clostridium pasteurianum which appears to regulate the efficiency of N(2) fixation in this bacterial species. The reticulo-stimulatory substance that has anti-tumor activity and is produced by Propionibacterium acnes appears to be polysaccharide and is probably associated with the cell wall. The neotype strains of the rumen bacteria Bacteroides amylophilus and Bacteroides succinogenes have been designated and described. Improved procedures for isolating and for in vitro labeling of bacterial DNA for bacterial DNA-DNA homology studies have been developed. A procedure was developed for pure culture of methanogenic bacteria using formate as the energy source. It allows determination of optimum conditions for methanogenesis. An essential enzyme for formate utilization in Methanobacterium formicicum electron transport has been partially purified. A growth medium for antibiotic susceptibility testing of anaerobic bacteria was developed and adopted as the U.S. standard, and Clostridium difficile toxin that is apparently related to antibiotic induced fatal diarrhea has been isolated. Three previously unreported and undescribed anaerobic bacteria are among the most frequently isolated species that occur in high numbers in human periodontal infections, indicating they may be of significance in the etiology of the disease. Twenty-one publications and 15 abstracts for scientific meetings.

CAUSAL FACTORS IN NEGLECT AND BATTERING - A PROSPECTIVE STUDY

W. Altemeier, Vanderbilt University, School of Medicine, Dept. of Pediatrics, *21st Ave. S. & Garland, Nashville, Tennessee* 37232

The purpose of this study is to determine the possibility of identifying, before the birth of a child, those mothers who will subsequently abuse or neglect their children and to specify the characteristics which distinguish parents who abuse or neglect their children from those who do not. A further aim of this research is to determine whether the provision of early and extended contact between the mother and her newborn infant during the lying in period can prevent later parenting disorders. The study, begun in 1975, has included physical and behavioral assessment of the newborn, infant-mother interaction, the incidence of parenting disorders and the collection of medical data. Preliminary findings give evidence that a flaw in the synchrony of infant-mother interaction from the first day or two after birth is predictive of high-risk mothers, and that extended contact between mother and infant can be significant in preventing subsequent abuse and neglect of the child.

WILDLIFE RESERVOIRS OF ARBOVIRUSES

T.M. Yuill, University of Wisconsin, Madison Campus, Agricultural Experiment Station, Dept. of Veterinary Science, *116 Agricultural Hall, Madison, Wisconsin* 53706 (0003021)

OBJECTIVE: Determine the occurrence and epidemiological significance of LaCrosse virus variants, and the relationship of these variants to mosquito vectors and wildlife hosts.

APPROACH: LaCrosse viruses will be isolated from wildlife hosts and mosquito vectors inn SW Wisconsin. These isolates will be tested to determine if plaque, mouse virulent (or attenuated), temperature sensitive, thermal stable or antigenic variants occur. These variants will be tested for their ability to infect wildlife hosts and to be transmitted by Aedes triseriatus, the natural vector.

PROGRESS: The role of medium-sized forest mammals in LaCrosse (LAC) virus epidemiology is being evaluated. LAC virus-infected mosquitos Aedes triseriatus infected red foxes. The foxes became infected and developed a viremia of 4-5 days duration and of sufficient amplitude to infect susceptible mosquitos which, in turn, transmitted the virus to susceptible chipmunks, a common forest host of this virus. Thus it appears that the red fox can potentially serve as a reservoir and dessiminator of LAC virus. Sentinel foxes placed in an endemic area became infected, indicating that transmission to foxes does occur commonly in nature. Experiments with captive raccoons revealed no viremia and it appears unlikely that they play a role as LAC virus reservoirs. It was shown that the snowshoe hare is capable of developing a significant viremia following experimental infection with Powassan (POW) virus. However, within the boreal forest in Northeastern Alberta, infection of snowshoe hares by POW virus was relatively uncommon during the period of our study. Our field studies did indicate that deer mice in this area were commonly infected with Modoc (MOD) virus. This virus also infects humans and we have evidence of antibiodies in local Indian population in the area. Ecological changes associated with mining of the Alberta tarsands appeared to increase deer mouse populations and the potential risk for increase of Modoc virus transmission in the area.

CASE-CONTROL STUDY OF NEOPLASIA AND STEROID CONTRACEPTIVES

R. Molina, Universidad de Chile, Jose Joaquin Aguirre Clinical Hospital, Dept. of Obstetricia y Ginecologia, *1058 Av. Bernardo Ohiggins, Santiago, Chile*

OBJECTIVE: To assess the carcinogenic risks of steroidal contraceptives.

APPROACH: A case-control study will be in progress for the next five years including every new patient with histologically confirmed cervical, endometrial and ovarian carcinoma. Two controls of the same age, socioeconomic level and origin will be chosen to answer the same questionnaire on contraceptive history as the women with carcinoma.

FREQUENCY OF NEOPLASTIC CONDITIONS IN A UNIVERSITY STUDENT POPULATION

B.J. Kaplan, Hebrew University of Jerusalem, Students Health Service, *13 Bialik St., Bet Hakarem, Jerusalem, Israel* (D-IARC-79-298)

The Students' Health Service provides, in conjunction with the Hadassah University Hospital, a comprehensive health service. Diagnoses and important symptoms are classified in accordance with the ICD (A), with the assistance of a computer. Students, currently about 7,000, are of both sexes from a wide variety of countries of origin, the vast majority being Jewish. The computer print-out includes, among others, register of all diagnosed cases of neoplastic disease in the age groups. The data base sheets in the patients' files provide background information. Quite a few cases of melanoma and squamous carcinoma of the skin have been recorded.

NATIONAL REGISTRY OF ORAL PRECANCEROUS CONDITIONS

K.R. Kanapathipillai, Inst. for Medical Research, Dept. of Stomatology, *Jalan Pahang, Kuala Lumpur, Malaysia* 0319 (D-IARC-79-405)

Preliminary studies indicate that as in oral carcinoma, there is predominance of Indian patients (72 percent) with oral precancerous conditions (OPC). OPC also seem to be closely related to oral habits. The peak age incidence was between 51-60 years (40 percent). The distribution of OPC was: (1) homogeneous leukoplakia (51.2 percent), (2) lichen planus (16.1 percent), (3) oral submucous fibrosis (15.2 percent), (4) speckled leukoplakia (11.9 percent), (5) erythroplakia (2.8 percent) and (6) smoker's keratosis (2.8 percent). Seventeen patients (8.8 percent) had two OPC. Indian females forming the largest part of this group (59 percent). Of these 17 patients, 76.5 percent had submucous fibrosis (SMF) and leukoplakia.

In Malaysia so far no case of SMF has been reported in Chinese or Malayan males. The WHO premalignancy index (PMI) score distribution was as follows: (a) 21.4 percent, (b) 31.7 percent, (c) 37.2 percent, and (d) 9.7 percent. The most common sites for OPC were (1) buccal mucosa (65 percent), (2) tongue (13 percent) and (3) labial commissures (9 percent). The labial commissures (85 percent), tongue (47 percent) and the buccal mucosa (43 percent) had the most ominous precancerous histological features. Similarly, the most ominous precancerous histological features (PMI) scores of (c) and (d) seen in the various OPC were: (1) erythroplakia (75 percent), (2) speckled leukoplakia (65 percent), (3) SMF (56 percent) and (4) homogeneous leukoplakia (48 percent); SMF is an important precancerous condition in the Indians. The cause of SMF is unknown and there is also no known treatment for this condition. This limited study so far indicates that oral lichen planus, smoker's keratosis, and white spongy naevus of the floor of the mouth do not appear to be precancerous conditions in Malaysians as they have been reported to be in population studies elsewhere. The differences could be largely due to the different patterns of oral habits.

RELATIONSHIP BETWEEN LEUKEMIA AND EXPOSURE TO DIAGNOSTIC RADIATION

T. Majle, National Inst. of Hygiene, Dept. of Radiation Protection & Radiobiology, *24 Chocimska St., 00791 Warsaw 36, Poland* (D-IARC-79-458)

The Tri-State Leukemia Study in U.S.A., 1962-1963, showed an excess of leukemias in adult males associated with an increased frequency of x-ray examinations. The purpose of the present study is to validate the results of the Tri-State Leukemia Study and to estimate exposure and dose of x-rays in 1,000 leukemia patients and in 1,000 controls chosen by random sampling from the Polish population. A retrospective survey provides information on the number and kind of x-ray examinations during the past 20 years. Information obtained from patients and controls is confirmed in hospitals, polyclinic records and archives. Exposure and dose of x-rays will be compared in both groups. A pilot study in Warsaw of 225 leukemia cases and 419 controls was completed in 1978. Some of the results show that the radiation load in leukemia patients may be higher than in relevant control groups. The results in children seem to indicate that children with leukemia were subjected to a higher number of x-ray examinations than the controls.

CAUSES OF DEATH IN THE DIFFERENT QUARTERS OF GENOA

R. Puntoni, Universita degli Studi di Genova, Inst. de Oncologia, Dept. of Epidemiology, *Viale Benedetto 15, Pad. B, 16132 Genoa, Italy* (D-IARC-79-323)

The city of Genoa (816,872 inhabitants) is subdivided into 25 quarters. The socioeconomic and environmental situation of these quarters is very heterogeneous and there are different levels of air pollution. The 20,000 deaths which occurred in the years 1970-71 are being analyzed by the quarter of residence, the cause of death and the last occupation. The purpose of this investigation is to define possible relations between environment (different levels of air pollution), occupation and cause of death, with particular reference to cancer of the respiratory tract.

EPIDEMIOLOGY OF LIVER CANCER IN YAMANASHI PREFECTURE

N. Maruchi, University of Tokyo, Faculty of Medicine, Dept. of Health Administration, *7-3-1 Hongo, Bunkyo-ku, Tokyo 113, Tokyo, Japan* (D-IARC-79-393)

The incidence of liver cancer in Japan is believed to be one of the highest in the developed countries of the world. While the mortality from this disease in Japan is comparatively higher in the western regions, the rate in Yamanashi Prefecture located in the central highlands of Honshu is very much higher. We are now developing epidemiological studies in collaboration with local investigators to search for specific aetiological factors. Preliminary correlation studies show a significant association of Schistosoma japonicum prevalence and liver cirrhosis, but not with primary liver cancer. A case-control study of patients with liver cancer and cirrhosis is now in progress.

MORTALITY STUDY OF SYNTHETIC GRAPHITE ELECTRODE MANUFACTURING WORKERS

K. Nakamura, National Inst. of Industrial Health, Dept. of Industrial Epidemiology, *2051 Kizuki Sumiyosityo, Kawasaki, Kanagawa, Japan* (D-IARC-79-351)

Studies of mortality among coke oven workers indicate that the excess of respiratory cancer is related to exposure to coal tar effluents. In the production of synthetic graphite electrodes, coal tar pitch is used as a binder for cokes (petroleum and coal). A cohort study has been carried out for the 5,025 workers who had or have been employed in all 14 electrode manufacturing plants in Japan. For the retired and employees who have left the industry, ascertainment of death is obtained from the family registry system in Japan and death certificate information is collected from the District Legal Affairs Bureau. By the end of 1974, 63 deaths from malignant neoplasms had occurred in the cohort, including 7 respiratory cancers. Follow-up continues prospectively.

CHILDHOOD LEUKEMIA IN NORWAY, 1963-1977

P.J. Moe, Universitetet i Trondheim, Dept. of Paediatrics, *7000 Trondheim, Norway, Norway* (D-IARC-79-443)

All cases of childhood leukemia diagnosed in Norway during the period 1963-1977 were collected by contacting hospitals, particularly all pediatric departments, and previously all departments of internal medicine. Information has also been obtained from the National Cancer Registry as cancer registration is compulsory in Norway. Information was obtained as to the type of leukemia, year of diagnosis and survival time. The first part of this study has already been published: Childhood leukemia in Norway from 1963-1974 with special emphasis on own material (Acta Paediatr. Scand. 65:529-533, 1976). The aim of the second part of this study is to register all current cases of childhood leukemia with emphasis on cell type, treatment regimen, results of therapy, and possible sequelae of the use of a high dose of methotrexate for almost all cases of acute lymphocytic leukemia diagnosed in Norway after 1975.

SPORADIC RETINOBLASTOMA IN RELATION TO PARENTAL AGE AND SEASONAL VARIATION

E. Matsunaga, National Inst. of Genetics, Dept. of Human Genetics, *Shizuoka-ken, Yata 1111, Mishima 411, Japan* (D-IARC-79-358)

Follow-up investigations of progeny of survivors of sporadic retinoblastoma revealed that they comprise two etiologically distinct groups, hereditary and non-hereditary. All bilateral cases belong to the hereditary group and they are due to dominant germinal mutations, while the majority (90-95%) of sporadic unilateral cases are non-hereditary, where the cause appears to be the same mutational event in the somatic (retinoblast) cells. Although a few investigations (including ours) suggest that paternal age may affect the occurrence of sporadic bilateral but not unilateral cases, the evidence is as yet not very convincing. We intend to clarify this point, together with the possible effect of seasonal variation upon the prosumed somatic mutations. Data concerning about 400 sporadic cases of retinoblastoma which occurred in 1970-1975 in Japan have already been analyzed, and new cases (approximately 100 per year) will be collected over the next several years.

SEROEPIDEMIOLOGICAL STUDIES OF HERPESVIRUS TYPE-2 AND CARCINOMA OF THE CERVIX IN ISRAEL

S. Leventon Kriss, Ministry of Health, Central Virus Lab., *P.O. Box 8255, Tel Aviv, Israel* (D-IARC-79-307)

The relationship between genital herpetic infection and squamous cell carcinoma of the uterine cervix has been substantiated by sero-epidemiological studies and by evidence of virus persistence in cervical tumor cells. Most studies proving the association between cervical carcinoma and HSV-2 were done in populations with high risk rates for this malignancy. Jewish women are at low risk for this disease. It was, therefore, considered interesting to compare the Jewish population studies with those in other demographic groups, namely Christians and Muslims in Israel.

PERSONALITY VARIABLES AND STRESS EXPOSURE IN CARCINOMA OF THE UTERINE CERVIX

P. Pancheri, Universita degli Studi di Roma, Inst. of Psychiatry, Psychosomatics, *30 Viale dell Universita, Rome, Italy* (D-IARC-78-314)

The objective of the study is the collection of standardized psycho-anamnestic data and psychometric evaluations on a large population of patients affected by carcinoma of the uterine cervix. Controls comprise women with non-neoplastic lesions of the cervix, a group with various psychometric disorders and 'normals', largely composed of nurses and relatives of patients in the same age range and social class as the carcinoma group. The hypothesis is that there are differences in mortidity rate according to factors like life stress events, stress induced by the social environment, and, more generally, factors inducing anxiety and depression.

ASPECTS OF CANCER OF THE UTERINE CERVIX IN JAMAICA

V. Persaud, University of the West Indies, Dept. of Anatomical Pathology, *Kingston 7, Jamaica* (D-IARC-79-340)

The crude incidence of cervix cancer (39.4 per 100,000 per annum) in Jamaica is among the highest in the world. The university departments of pathology, social and preventive medicine and obsterics and gynecology have been undertaking studies on the incidence, aetiology, early detection and morphology of uterine cervix cancer in Jamaica. Incidence figures are obtained from the Jamaica Cancer Registry, Dept. of Pathology, U.W.I., for a well-defined metropolitan population with adequate diagnostic facilities. Early detection by cytology screening in family planning clinics has shown a prevalence of 5.7 per 1,000 women whereas the rate in a low-income, high-risk, general population of 'well' women was 18.0 per 1,000. This discrepancy appeared to be due to the fact that the family planning women were of low parity (para 0-3) and therefore were not at high risk of developing cervix cancer since both groups were matched for age, race and socioeconomic background. A retrospective interview study was carried out on 300 histologically proven cases of cervical carcinoma and 390 'well' controls matched for age, race, and social class. The controls were drawn from a low-income, high-risk general population of women who were cytologically negative for cervix cancer. The questions asked concerned their marital status, number of pregnancies, age at first pregnancy and first coitus, number of coital partners and the circumcision status of these partners and sexual hygiene. The statistically significant factors were grand multiparity, promiscuity, poor sexual hygiene and early age at first coitus and first pregnancy. Studies on the epidemiology and early detection of cervix cancer in Jamaica are still progress.

PROSPECTIVE STUDY ON THE EPIDEMIOLOGY OF GESTATIONAL TROPHOBLASTIC DISEASE IN THE NETHERLANDS

J.G. Stolk, Katholieke Universiteit Nijmegen, Dept. of Obstetrics & Gynecology, *Erasmuslaan 4, Nijmegen, Netherlands* (D-IARC-79-414)

In 1975 in Holland there were 179,155 births in a population of 13.8 millions. The total number of pregnancies is estimated to have been 250,000. Central registration of all cases of gestational trophoblastic neoplasm started in 1976. The frequency of molar pregnancies is unknown. The main objectives of the present study are to obtain information about the epidemiology of gestational trophoblastic neoplasms in the Netherlands and to improve the prognosis of choriocarcinoma by early therapy. All cases of molar pregnancy in Holland will be registered and human chorionic gonadotropin determinations on all cases of trophoblastic neoplasm will be centralized in the Radioimmunoassay Laboratory in Nijmegen.

STUDY OF RETINOBLASTOMA IN JAPAN AS A POSSIBLE POPULATION MONITORING SYSTEM FOR ENVIRONMENTAL MUTAGENS

T. Sugahara, Kyoto University, School of Medicine, Dept. of Experimental Radiology, *Yoshida-Konoecho, Sakyo ku, Kyoto 606, Kyoto, Japan* (D-IARC-79-357)

Because an increasing number of environmental mutagens have been detected by laboratory screening methods, the need to monitor human population directly for mutational risk has been emphasized by many geneticists. Recent studies by Knudson give hope that certain malignant neoplasms might be used to assess somatic mutation rates. According to Knudson, the age at first diagnosis of these diseases may be related to the annual somatic mutation rate. Thus the data on the age at first diagnosis of unilateral and bilateral retinoblastoma have been collected throughout Japan. Since 1975 the data have been obtained by a nationwide registry of the disease in cooperation with the Ophthalmology Society of Japan. A first report suggesting an increase of mutation rate in Japan has been published (Mutation Research 30, 137, 1975). The study continues.

CARCINOMA OF THE LUNG IN ICELAND - EPIDEMIOLOGICAL AND CLINICAL STUDY

H. Thorarinsson, Haskola Islands, Landspitalinn, Dept. of Surgery, *Baronsstigur, Reykjavik, Iceland* (D-IARC-79-256)

The incidence of carcinoma of the lung has been increasing over the last two decades, and there is a definite correlation with the increased sale of cigarettes which occurred some twenty years earlier. Tobacco consumption of Icelanders increased more than hundredfold during the years 1910-1949. In the period 1931-1954 only 34 cases of lung cancer were recorded, whereas during the periods 1955-1964 and 1965-1972, respectively 156 and 224 patients with lung cancer were reported. There is a preponderance of large cell carcinomas and small cell anaplastic carcinomas in this series, epidermoid carcinoma comprising only about 20%. Smoking habits are known for 75% of the patients admitted to the department of thoracic surgery: 90% of the patients with epidermoid carcinoma had been heavy smokers (20 or more cigarettes a day) for ten or more years; 80% over twenty years. The corresponding figures for the other histological types are: Small cell anaplastic carcinoma 77%; 70% over twenty years; adenocarcinoma 36%; large cell carcinoma 69%; 64% over twenty years. Only 3.5% of the patients with epidermoid carcinoma had never smoked, whereas 36% of the patients with adenocarcinoma had never smoked. In the group of patients with large cell carcinoma and small cell anaplastic carcinoma there was not a single patient who had never smoked.

THE EFFECT OF CHANGING DIETARY HABITS ON ESTROGEN PROFILES IN GREECE

D. Trichopoulos, University of Athens, School of Medicine, Dept. of Hygiene & Epidemiology, *Odos Panepistimiou 30, Athens 609, Greece* (D-IARC-79-233)

Diet is one of the factors that may be responsible for the different incidence of breast cancer in urban and rural areas of Greece. If estrogen fractions are important in the aetiology of breast cancer, then diet should have an effect on the estrogen profiles. Urine and blood samples were collected from about 120 student nurses who came to Athens from rural areas to study nursing. Since the diet in the School for Nurses is different from that in the rural areas of Greece, third year students should be different from first year students with respect to estrogen profiles. Blood lipids were also measured because their relation to diet seems established.

PARITY AND ESTROGEN PROFILES

D. Trichopoulos, University of Athens, School of Medicine, Dept. of Hygiene & Epidemiology, *Odos Panepistimiou 30, Athens 609, Greece* (D-IARC-79-231)

To account for the major features of the epidemiology of breast cancer, a hypothesis has been developed linking breast cancer risk to estrogen metabolism. The hypothesis postulates that women who, during the early years of reproductive life, metabolize a low proportion of their estrogen to estriol are at high risk of breast cancer during the remainder of their lives (Lancet 1: 604-606, 1969). Since age at first pregnancy is an important risk factor for cancer of the breast, a relation between parity and estrogen profiles should be expected according to this hypothesis.

APPROACH: Urine or blood samples are being collected from 150 primiparae and 150 nulliparae 15-29 years old. Estrogen profiles, other hormone metabolites and several biochemical parameters are being measured in Melbourne, Boston or Athens.

ESTROGEN PROFILES IN WOMEN OF URBAN AND RURAL AREAS OF GREECE

D. Trichopoulos, University of Athens, School of Medicine, Dept. of Hygiene & Epidemiology, *Odos Panepistimiou 30, Athens 609, Greece* (D-IARC-79-232)

The incidence of breast cancer is considerably higher in the rural areas of Greece than in Athens. According to this hypothesis, young women in rural areas should have more favourable urinary estrogen profiles than women living in Athens. Urine samples were collected from about 120 young women, residents of Athens and of a rural area in southern Greece, and estrogen fractions and other hormone metabolites were measured in Melbourne or in Boston.

STOMACH AND OTHER CANCERS IN POZNAN

T. Walter, Akademia Medyczna, Inst. of Social Medicine, Dept. of Epidemiology, *Fredry St. 10, 61701 Poznan, Poland* (D-IARC-78-410)

Following preliminary investigations to determine whether all cases of cancer have been notified as required by law, it is proposed to examine in greater detail the characteristics of cases of gastric cancer diagnosed in Poznan (population 500,000) in 1967-

1976, in particular age, sex, social class and conditions of work.

PROSPECTIVE STUDY IN RELATION TO OCCUPATIONAL EXPOSURE TO VINYL CHLORIDE

C.P. Tuinman, Shell Nederland Raffinaderij B.V., Industrial Medical Services, *Vondelingenweg 601, Rotterdam, Netherlands* (D-IARC-79-421)

Vinyl chloride (VC), under normal temperatures and pressures of gas, can easily be polymerized to polyvinyl chloride (PVC), a white solid material. Apart from fire and explosion risk and a quickly appreciated narcotic effect, acro-osteolysis and soft tissue changes have also been described. Following an epidemiological study by Maltoni in 1974, reporting a cluster of cases of angiosarcoma of the liver in men who had previously worked as cleaners of reactors, a prospective study on VC-workers in this polymerization plant has been set up, comprising the tracing of medical data on previous VC-workers and a biannual physical and biochemical investigation of the present VC-population. Findings are related to the degree of VC-exposure as measured either by personal monitoring or fixed point air sampling.

HERPES VIRUSES IN CHILDHOOD CANCER

G.T. Stematsky, Ministry of Health, Central Virus Lab., *P.O. Box 8255, Tel Aviv, Israel* (D-IARC-78-296)

Groups of children with various tumor types are being tested by the indirect immunofluorescence test for the presence of antibodies to Epstein-Barr virus (EBV), cytomegalovirus (CMV), herpes type 1 and 2 and varicelia-zoster (VZ) in order to obtain information on primary infections and on frequency of reactivation or reinfection with these viruses in sick as well as healthy children. Correlation analysis of serological profile with age, sex, ethnic origin and clinical data will be carried out.

CANCEROUS DISEASES OF THE LARGE BOWEL

K. Schwarz, University of Otago, Christchurch Clinical School, Dept. of Community & Preventive Medicine, *Hagley Ave., Christchurch, New Zealand* (D-IARC-79-426)

The aim of the study is to define the epidemiology of cancers in Christchurch and Canterbury against the background of the epidemiology of these cancers throughout New Zealand, and to identify the individuals and groups at risk from this group of cancers. The following factors are being investigated: demography, signs and symptoms, investigations, family and contact history, other colonic pathology and general medical conditions, pathology, postoperative course and hospitalization and surgical aspects.

INTERNATIONAL CANCER MORTALITY STATISTICS

M. Segi, Segi Inst. of Cancer Epidemiology, *Yomeicho 2-5, Mizuho-Ku, Nagoya 467, Aichi, Japan* (D-IARC-78-342)

In our previous publications, statistics of cancer mortality in 24 countries were compiled from data provided directly from the central bureaus of statistics in 24 countries. Currently, we compile and analyse the statistics of international cancer mortality using the data printed in the World Health Statistics Annuals published by WHO.

MALIGNANT NEOPLASMS IN TUBERCULOSIS PATIENTS

R. Steinitz, Israel Center for Registration of Cancer & Allied Diseases, *18 20 King David St., Jerusalem, Israel* (D-IARC-79-303)

A unique opportunity of having two population-based registries under one roof was used for a preliminary investigation of tuberculosis and lung carcinoma which suggested that tuberculosis patients are at a higher risk of developing lung cancer. Possible causes for the high risk were discussed: scar carcinoma, the effect of large amounts of radiation (diagnostic procedures) and the carcinogenic effect of anti-tuberculosis drugs. If radiation is a cause of higher risk, the bulk of the resulting lung carcinomas will have appeared by now, as diagnostic and therapeutic procedures have changed. On the other hand, anti-tuberculosis drugs, especially isoniazid, which has been shown to have carcinogenic effects in animals, have now been in use for a probably sufficient length of time to show their specific carcinogenic effects, not necessarily limited to lung cancer, in tuberculosis patients. The purpose of the study is to re-examine the risk of tuberculosis patients of developing lung and other cancers and to look for differences in the cancer experience of tuberculosis patients according to changes in diagnostic and treatment policies. This is a record linkage study based on the Israel Cancer Registry and the Israel Tuberculosis Registry, supplemented by information from hospital and regional chest clinic records. The Tuberculosis Registry has approximately 55,000 names, starting in 1948, and also includes patients diagnosed before this date. The information on the tuberculosis patients will be extracted from individual records, from the Tuberculosis Registry, hospitals and chest clinics. Information on validation of diagnosis of tuberculosis, date of diagnosis of tuberculosis, localization of the tuberculous process, type and periods of anti-tuberculosis therapy, anatomical site and histology of cancer, date of diagnosis of cancer, activity of the tuberculosis at the time of the diagnosis of the tuberculosis and at the date of diagnosis of the cancer and cause of death will be sought.

EPIDEMIOLOGICAL STUDY OF ACUTE CHILDHOOD LEUKAEMIA IN RELATION TO SEASONAL DISTRIBUTION, CLUSTERING, FREQUENCY OF CHLOROMA, G-6-PD

L. Zannos Mariolea, University of Athens, Blood Research Lab., Dept. of Pediatrics, *Odos Panepistimiou 30, Athens 608, Greece* (D-IARC-79-237)

Retrospective studies of acute childhood leukaemia in Greece have shown an increased occurrence of new cases during the spring months and a significant yearly variation in the percentage of non-lymphoblastic forms. The main objectives of the present study are: (1) Characterization of the seasonal distribution of acute lymphoblastic leukaemia (ALL) and acute non-lymphoblastic forms; (2) search for clustering of cases in space and time and clustering in time of cases with ALL which have a leukocyte count over 20,000 per cmm; (3) determination of the frequency of occurrence of the chloromatous form of acute leukaemia (this variant is increased in Africa and Turkey); (4) estimation of frequency of leukaemias, lymphomas, neuroblastomas and other malignant tumours among hospital admissions and of glucose-6-phosphate dehydrogenase (G-6-PD) deficiency and beta-thalassaemia trait among children with acute leukaemia (Do these traits confer increased resistance against acute leukaemia?).

LEUKEMIA INCIDENCE AMONG WORKERS CHRONICALLY EXPOSED TO SOLVENTS AND CHEMICALS

M.B. Aksoy, Istanbul Universitesi, School of Medicine, Dept. of Internal Medicine, *Bayezit, Istanbul, Turkey* (D-IARC-79-558)

The development of leukemia among shoe factory workers, particularly those chronically exposed to benzene, is being examined. follow-up study covering 2-17 years has been carried out on 44 pancytopenic patients who had been subjected to high concentrations of benzene (150-650 ppm) in adhesives for periods ranging from four months to 15 years. The average benzene content of the adhesives was 50%. Leukemia developed in six of the 44 pancytopenic patients, showing evidence of a leukemogenic effect of benzene in man (Blood, 52, 285-92. 1978). Follow-up continues. A study on the occurrence of malignancies among workers exposed to vinyl chloride monomer in a petrochemical plant at Yarimca, Izmit, began in 1978. Futher studies among workers in textile indstries, where solvents and chemicals are used, and in asbestos and cement pipe factories will be undertaken during 1979 and 1980.

HISTORICAL DATA BASE FOR ONE COMPANY IN THE PETROLEUM INDUSTRY

M.R. Alderson, Inst. of Cancer Research, Division of Epidemiology, *Clifton Ave., Sutton SM2 5PX, England, United Kingdom* (D-IARC-79-692)

This project will set up a comprehensive file to examine future queries about the influence of work in a particular process upon mortality from specific diseases. Specific job histories will be obtained for all individuals who have worked at two large refineries for more than one year since these refineries were established. A comprehensive job history will be abstracted and the file will accumulate at the same time data on the plants and processes at each of the refineries including designation of the major variation in the raw materials, intermediaries, and products from each process. Individuals leaving the industry will be traced and the intention is to provide death details for all individuals who have died. This file of data will be primarily used as a computer-based retrieval system to check specific queries about health-risks from various processes. The primary approach will be to relate observed mortality to expected mortality taking into account age, sex, calendar period, and location in the country.
